CIRCUIT DESCRIPTION

What is Compu-Phonic Synthesizer?
(Features of Compu-Phonic Synthesizer)

Conventional Synthesizer

Compu-phonic Synthesizer

2-1. Control Section:
- Switches and Sliders -
Sliders and switches on the control panel are now not for the production of the synthesizer control signals directly, such as the production of the time constants, ON/OFF switching, etc. They now serve only to letting the computer know of their positions or the states as they are put on the Control Panel.

2-2. Voltage Controlled Synthesizer Circuits:

Such parameters as the time constant, ON/OFF switching, or their signal levels, etc. have so far been produced on the control panel there are sliders and switches to obtain directly of such.

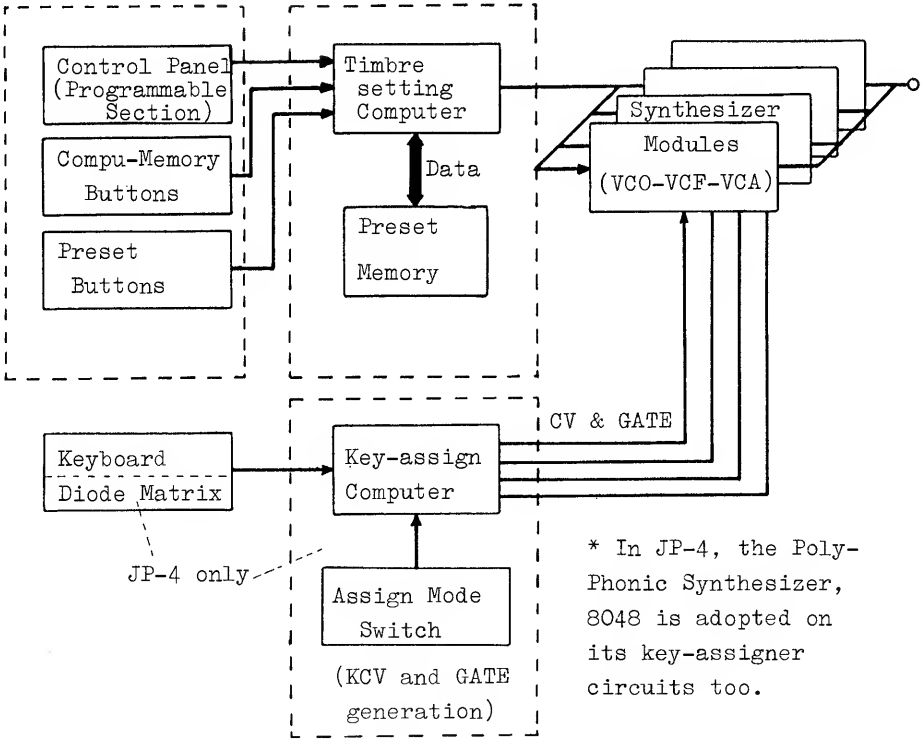

These are, however, now produced by the computer's internal circuits, and the synthesizer circuits are under fully voltage controlled, programed and/or given by the computer, with self-contained transconductance amps or analog switches, etc. However, the circuit and function themselves of VCO, VCF, VCA etc. of the synthesizer's main circuits are just as the same as before with those on the conventional synthesizer.

1. Operational Principle:

In the conventional synthesizer, the circuits (VCO, VCF, VCA, etc.) are directly controlled from the control panel.
In the compu-phonic synthesizer, it is the computer that comes in between and provides control voltages suitable to those VCO, VCF, VCA, ENV GEN, etc.

2. Hardware:

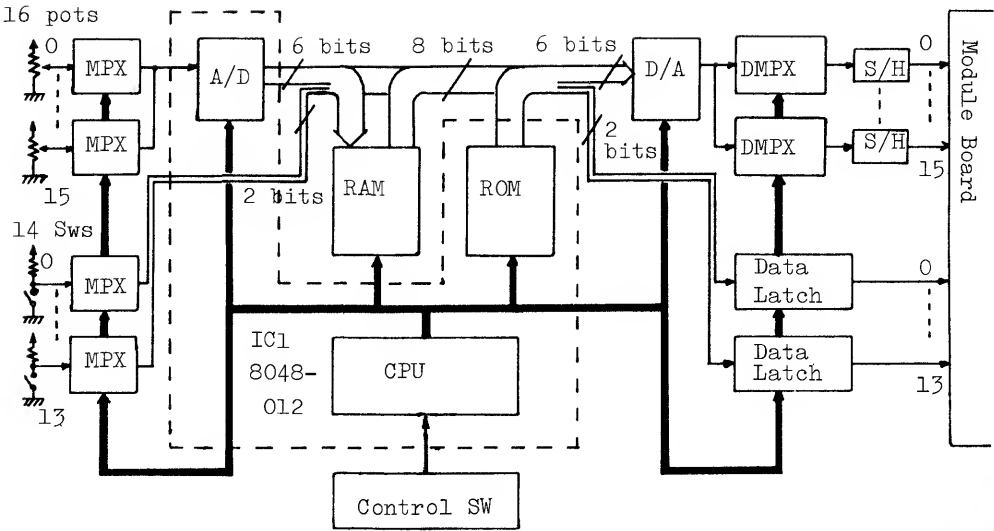

Compu-Phonic Synthesizer is composed of the "Synthesizer Control Circuits" with μ PD8048 as its central point and the "synthesizer circuits" which are fully controlled by voltage.

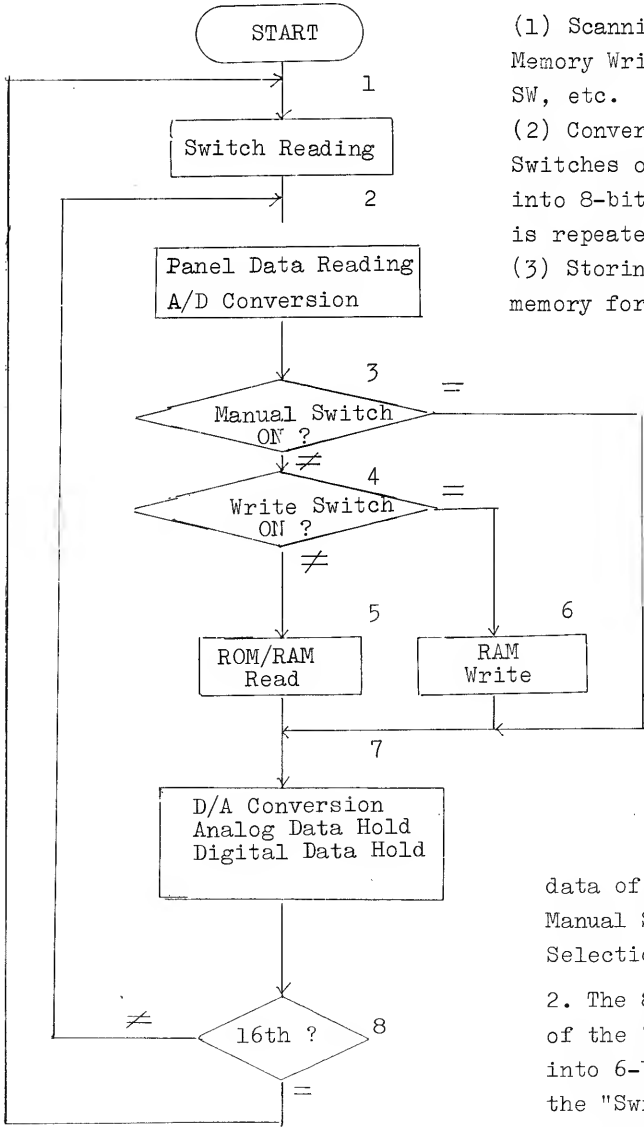

Function of

Mother Board

In the Mother Board included are the microcomputer 8048-012 and its peripheral circuits. (refer to the General Block Diagram when reading the following)

Mother Board Block Diagram

8048-012 Flow Chart
(JP-4, PROMARS)

- (1) Scanning of all the switches on the Control Panle such as Memory Write SW, Manual SW, Compu-Memory SW, Pre-Set Selection SW, etc.
- (2) Converting the Analog signals obtained from Sliders and Switches of the Programmable Section on the Control Panel, into 8-bit digital data (A/D conversion). (This data reading is repeated 16 divided times to complete them all).
- (3) Storing these A/D converted data of the POTs and SWs into memory for use afterward upon retrieval.

- (4) Converting back again these digital data into analog voltage (D/A conversion) to send them out into Synthesizer Modules. All these functions stated above are performed under the control of 8048-012.

-Functions of 8048-012-
(Tone color setting controller)

These operations of 8048-012 are shown in the flow chart. The 8048-012 repeats such flow chart cycle. The following numbers refer to those in flow-chart.

1. When the power is turned on, 8048-012 starts its reading and puts into memory the data of the positions it reads of Memory Write Switch, Manual Switch, Compu-Memory Selection Switch and Preset Selection Switch.

2. The 8048-012 takes in at first the voltage data of one of the "Slider pots" on the Control Panel and converts it into 6-bit digital data. At the same time, it reads out the "Switch Position" on the Control Panel and converts it, too, into 2-bit digital data. The two data thus obtained are combined to make a total 8-bit data. These are held there for a while.

3. If the MANUAL Switch was OFF at step 1, the program proceeds to step 4, or if ON, to 7. During this process, the data obtained in step 2 is maintained.

4. When the Memory Write Switch was OFF at step 1, the program goes to step 5, if ON, to 6. The step 2 data is still maintained.

5. Based on the data being held in step 2, the 8048-012 accesses to either RAM (Random Access Memory) when a switch in Compu-Memory was pushed in, or ROM (Read Only Memory) when one of Preset Switches was in. It then reads out from the address corresponding to the switch depressed, the data to give control to the Synthesizer Modules.

6. Based on the data in step 1, it writes the data held in step 2 to RAM, selecting the address over there which is corresponding to the switch position on the COMPU-MEMORY SWs.

7. The 8048 divides the 8-bit data (data in step 2 or data retrieved in step 5) into two formats: 2-bit switch data and 6-bit slider data. The 6-bit data then proceeds to D/A conversion. Those two signals of analog converted voltage and of switches are fed to the Module Boards.

8. The 8048 checks to see whether it completed all 16 cycles to read out all data divided into 16 at the previous stage. If all are completed it goes back to step 1. If not, to 2.

-Switch Reading-

The 8048-012 scans the matrix made of the diodes and switches on the Control Board F to find out which switch is depressed among those of WRITE through MEMORY PROTECT.

1. Diode-Switch Matrix

On the Control Board F, Switches (each accompanying diode) are grouped into 4 blocks consisting of 2 to 8 switches. These blocks are then connected through the data bus to DB0, DB3, DB4, DB6 on 8048-012. The blocks are also routed through to the pins of P20-P27 on Port 2 of 8048-012. They are then making a matrix. (refer to the Circuit Diagram, Control Board F)

2. To Scan the Switches

The 8048-012 outputs "L" onto DB0 alone and "H" on all other DB1-DB7.

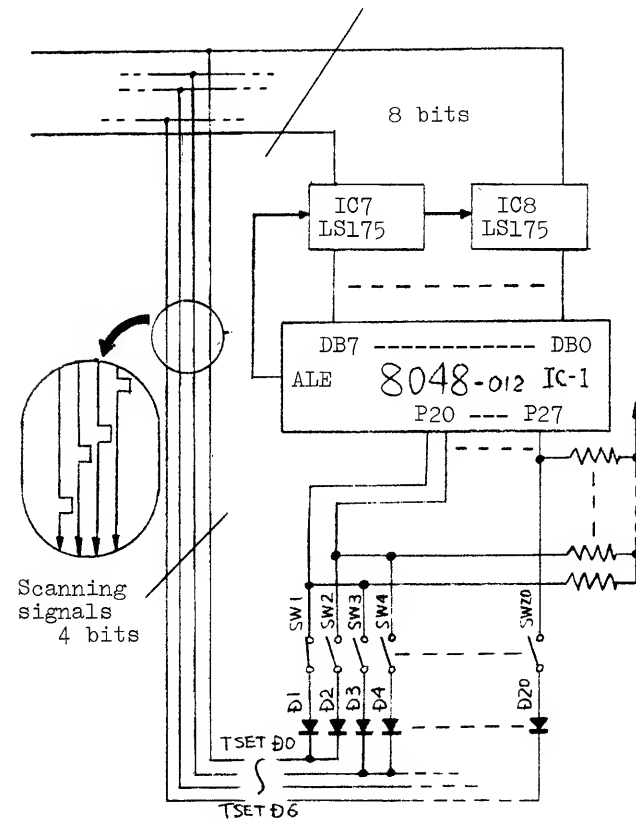

They are out on the data bus and latched on IC7, IC8, 74LS175 by the pulses from pin ALE (Address Latch Enable) to be output onto D0-D6 of TSET.

Next, 8048-012 reads the Port 2 (P20-P27). If it finds here that the P20 alone "L" while all others on "H", then it can know of that the SW1 is on.

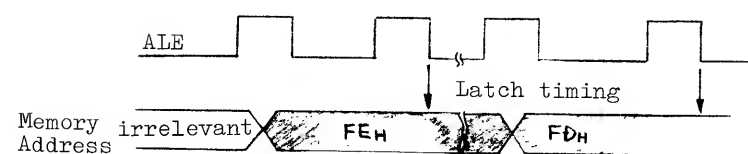

The above process is repeated to go over all of DB0 to DB7, but four of them are connected to switches.

MEMORY WRITE Switch (SW1) is so wired that it is only enabled when Compu-Memory selection switch (SW21) being depressed at the same time.

(see circuit diagram, CONTROL BOARD F)

Switch Scanning Signal Flows

DB Data Latch Timing

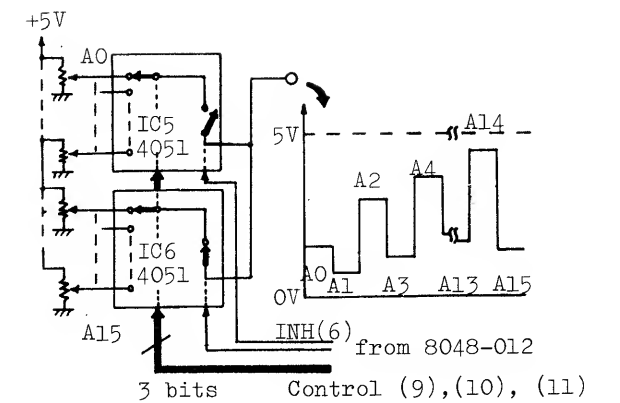

- Reading of CONTROL PANEL - The PROGRAMMABLE SECTION

The 8048-012 reads the patching on the Control Panel and converts them into digital data of 16 bytes. (1 byte = 8 bits)

Of the Control Panel, the section named "PROGRAMMABLE" consists of 16 pots and 14 switches, these 16 pots produce 16 different kinds of analog voltage varying between 0V to 5V. The 14 SWs, on the other hand, produce binary digital data of "H" or "L", given by +5V or 0V, respectively. The 16 analog voltages that come in parallel to each other are re-arranged through the analog multiplexer (MPX) IC5, IC6 4051, to be put on a single line in time sequence.

These outputs of the MPX go into the A/D converter (will be described later) to become 6-bit data of 16 kinds.

The 14 binary data of the switches are also re-arranged into 2 groups of 7 kinds (total 14) with each group entering each respective MPX IC3, IC4 where they are made to 2-bit data and be output from there in time sequence as above. These 6-bit and 2-bit data are combined to become an 8-bit data. That is to say, that, the patching first made on the Control Panel are become to be represented by all digital data of 16 bytes in all. (refer to Memory Map on page 13)

Multiplexer

IC5, IC6, 4051 can be regarded as the same to a rotary switch provided with one more switch on itself as shown above.

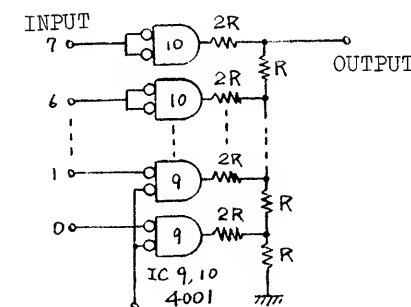

Port 1 of 8048 outputs both the Address signal (Control A, B, C, Pins 9, 10, 11), which also serves as switch for 4051 itself for INPUT/OUTPUT Address data, and Chip Enable Signal (INH, Pin 6).

(There are 4 of 4051. Pins 9, 10, 11 of all four are connected through the same lines)

- D/A and A/D Conversion -

1. D/A Converter

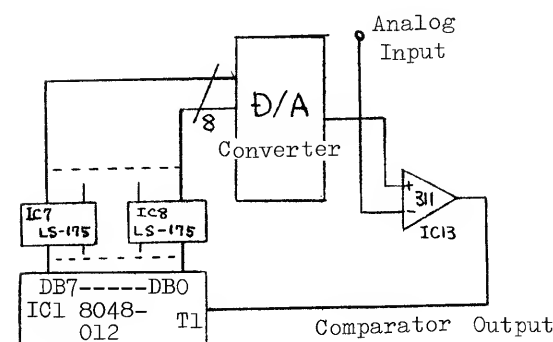

The D/A Converter used on the Mother Board is the one called "R-2R type". The converter here is only making use of higher significant 6 bits among those of 8 bits given here, leaving the least significant 2 bits unused.

D/A Converter

2. A/D Converter

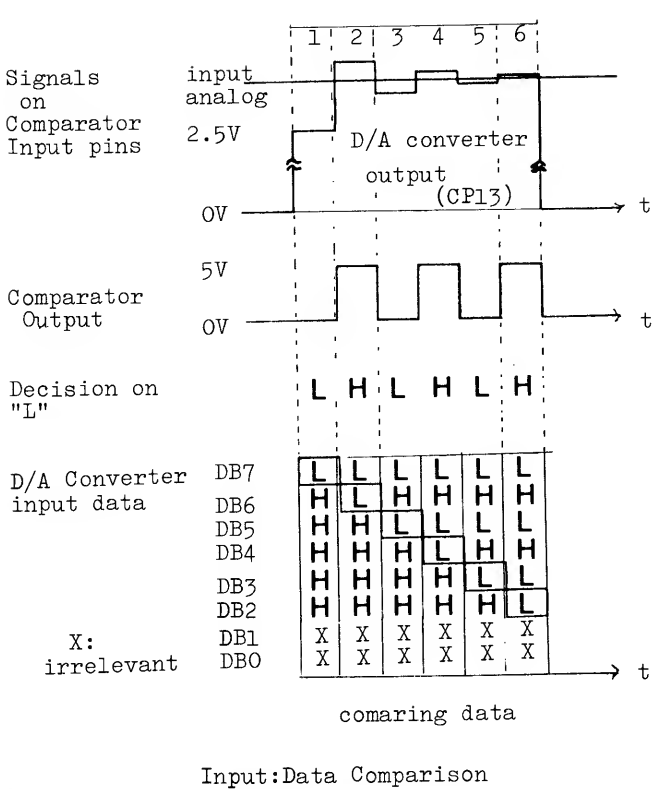

The A/D Converter on the Mother Board is referred to as "Successive Approximation Type Converter" which make use of the D/A converter and a comparator. To proceed on with conversion, 8048-012 starts deciding the data at first for the most significant bit, then down to those lesser significant bits. IC9, IC10 serve as an inverter, making the input to follow negative logic. The output is +5V maximum, therefore, when it receives the input LLLLLLXX, or 0V minimum when HHHHHHXX. (XX are for those least significant bits that are made nil.)

A/D Converter

(Numbers 1-6 below in this section refer to those at top in figure right)

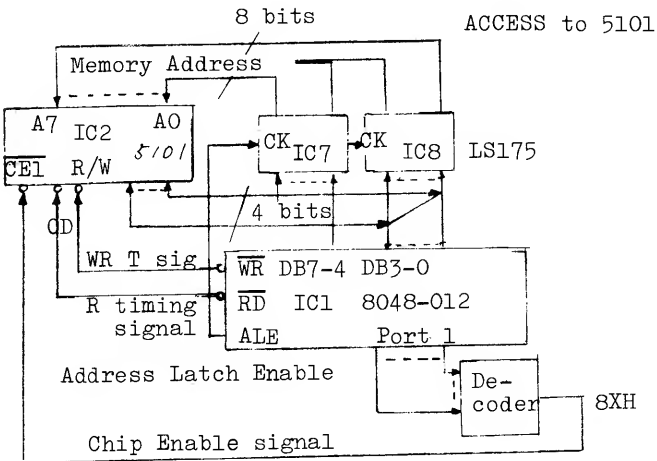

The 8048-012 tries at first putting DB7 to "L", thus making the digital data at first to LHHHHHXX, tentatively. These are latched on LS175 by the pulse from ALE pin, then out onto the D/A converter. On the one hand, 8048-012 reads the output level of the comparator, IC13 311, through T1 pin. It makes comparison between these two, of the A/D input and of D/A converted output to LHHHHHXX (= 2.5V). If the A/D input is to be as shown in figure (a straight line a little over 2.5V), the comparator finds that the D/A converted output LHHHHHXX(2.5V) is less than that of A/D input. It is to instruct 8048 to decide that the "L" previously put on tentative base can be firm so that "L" is to remain on DB7 hereafter. Now, 8048 turns to DB6 in putting here again "L" tentatively, to output LLHHHHXX. With this data, the D/A output becomes higher than the A/D input as in step 2 on figure. It makes the output of the comparator 311 turn to "H". That means, that 8048 has now to decide that DB6 in "L" is too large, so it must be reset back to H again. The same process continues through the lesser significant bits, as on step 3-6 on figure.

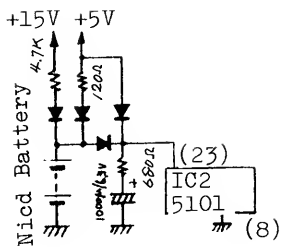

Each time, the D/A output approaches successively nearest to the A/D input voltage. And finally, when 8048 completes them all for DB7 to DB2 for bits, it has decided the data on the nearest approximation to be equal to that of input of the A/D converter.

- Memory -

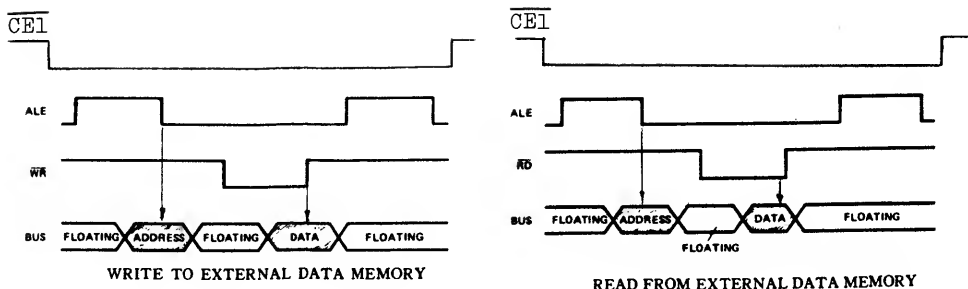

Here provided on this Compu-Phonic Synthesizer are "CMOS RAM", IC2, 5101 for memory of the tone color (timbre) data to be used on Compu-Memory and ROM which resides in 8048-012 for use on PRESET mode.

8048-012 outputs from Port 1 the address data to turn the Chip Enable (CE1) to "L" on 5101. Then, 8048-012 outputs the pulses from ALE pin to make LS175 (IC7, IC8) latch the data and define the memory address upon 5101. While the memory address being defined by LS175, 8048-012 outputs onto DB0 to DB3 the data to be written. These data are then written onto 5101 by turning WR to "L", and are read by 8048 through DB0 to DB4 when RD is "L". The digital data on the Control panel are 8 bits format. However, when made access to 5101, they are divided into 2 by 8048-012. (Because 5101 handles 4-bit quantities.) 5101 is backed up by the NiCd battery for protection of its memory. The NiCd battery will be fully recharged for more than 48 hours. The memory on 5101 are also protected for an hour by the electrolytic capacitor (1000mfd 6.3V) just in case when the battery is removed for replacement or other.

DC Supply for 5101

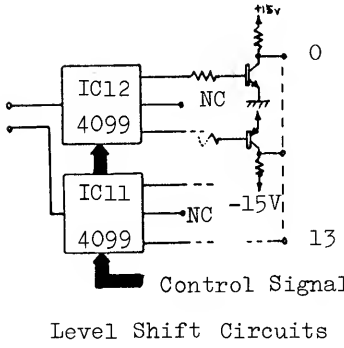

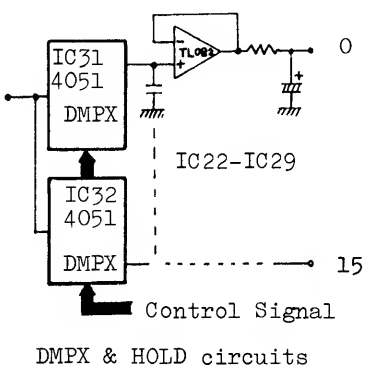

5101 READ/WRITE CYCLE

-- GENERATION of CONTROL SIGNALS to MODULE BOARD(S) --

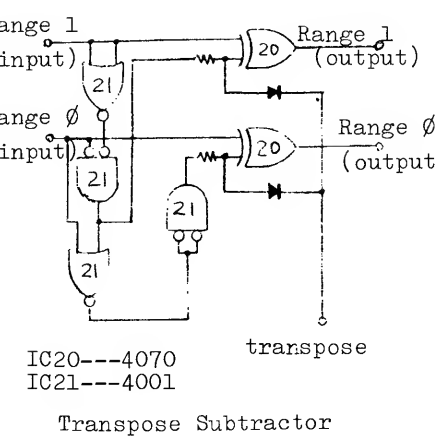

The control data that were A/D converted to kinds of analog voltages and 14 kinds of binary 8-bit digital data are re-converted to 16 signals before they are sent to the Module Board(s).

1. The 8048-012 reads out these digital data of 16 bytes successively from RAM or ROM. Upper 6 bits (DB7 to DB2) among them are made to analog voltage thru D/A converter and are put on a single line in time sequence and are sent to 16-output analog demultiplexer, DMPX IC31, IC32, 4051.

DMPX here is to separate the input data into 16 at the control signals from 8048-012 (IC31, 32, pins 6, 9, 10, 11). They are held at TLO82, IC22 through IC29 to be sent out to the Module Controller and the Module Board.

2. The lower 2 bits data, DB1, DB0 are fed in time sequence to the input pin of each respective address data latch 4099, IC11, IC12. The two 4099s latch them in separate 7 groups under the control signals from 8048-012 (to pins 4, 5, 6, 7). The outputs of 14 kinds go into the level shift circuit following 4099 where they are shifted into levels each suitable for the purpose to each. (Section surrounding Q3-Q14.)

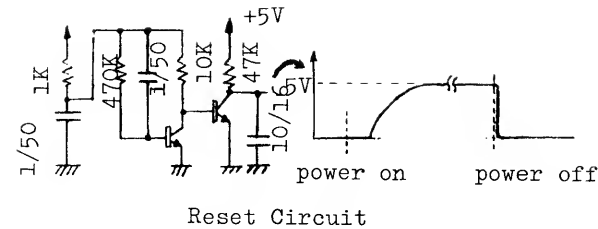

3. Of the 14, those of VCO-WAVE 1, ϕ and LFO-WAVE 1, ϕ are fed to the Wave form selector, IC19, IC20 and LFO Select Decoder, IC33, IC34 to receive each respective decoding. VCO-RANGE 1, ϕ go into Transpose Subtractor where the contents of the 2-bit data of RANGE 1, ϕ are converted when the Transpose Input is turned to "L". Refer to Table for what conversion is meant on this transpose. In effect, it is to go down by 1 octave on VCO range as shown by arrows. Thus, the Switch control signals in 14 kinds become to control the Module Boards after passing through these circuits as above.

Transpose by the Subtractor					
TRANSPOSE		H	ϕ	L	
	RANGE	RANGE	RANGE	RANGE	
32'	1	ϕ	1	ϕ	
16'	L	H	L	H	
8'	H	L	H	L	
4'	H	H	L	L	

CIRCUIT DESCRIPTION

- OTHERS - Reset Circuit

The circuit is to protect 8048-012 from running program inadvertently. When RESET pin 4 is turned to "L," it makes 8048-012 to reset back to the initial state. This is also connected to 8048-011 through the common line. (8048-011, JP-4 only)

- MODULE BOARDS -

Included here are VCO, VCF, VCA and 2 ENV GENERATORS.

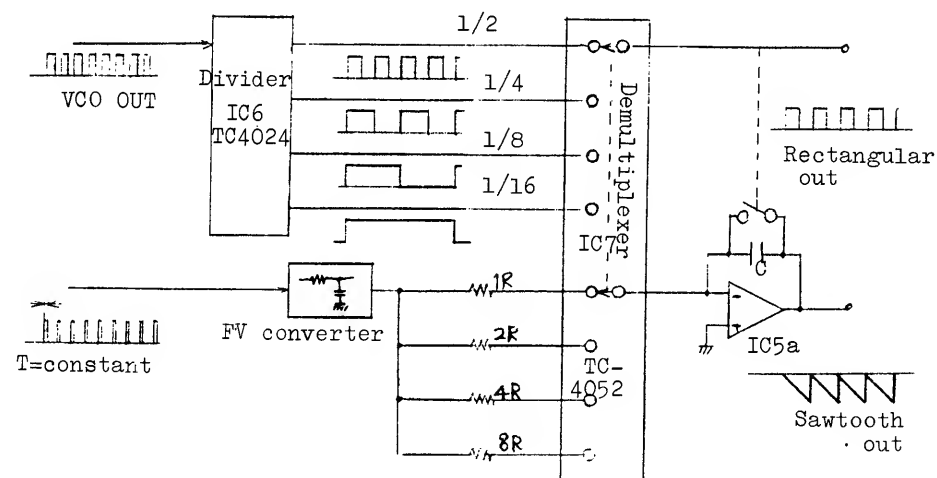

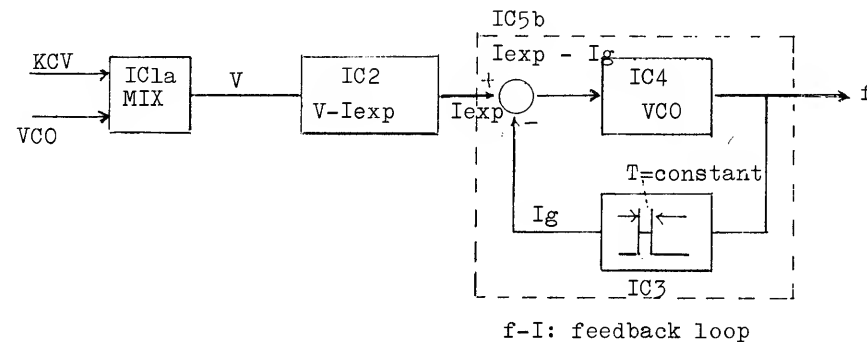

1. VCO and its Peripherals

IC1a(pin 1,2 and 3)makes the vibrato voltage VCO CONT and keyboard key voltage KCV mixed and sends them out onto the antilog transistor IC2 which outputs antilog current from pin 9. This antilog current is then compared at the Comparator IC5b(pin 5,6, 7) with the current flowing in from pin 6 of IC4 thru R118.

The output of the comparator IC5b is made to control the VCO generator oscillation frequency produced from IC4, Gate IC. Here, however, the VCO has to make the oscillation in such frequency that it always keeps the difference at zero in values between the current I_g from pin 6 of IC4 and the antilog current I_{exp} from the antilog IC2.

The VCO outputs are in the pulse form of the constant width converted by the one shot multivibrator IC3(555).

It is therefore necessary to double the number of pulses if the antilog current is doubled. IC5b watches this to keep the balance at this pin 6. And, if losing the balance, it sends an additional voltage onto VCO to make it regain the balance. These are the process how to output the frequency which is antilog-proportional to the input voltage. The pulse output here is of so narrow width as yet. It is necessary therefore to provide further wave conversion. IC6 is a frequency divider. IC7 is a multiplexer to make selection from those divided frequency,

IC5a generates sawtooth waveform synchronized to that of the selected frequency. The amplitude of the sawtooth waveform is kept constant by choosing either of R18-R24 by the multiplexer IC7 regardless of any change made at the tone feet. On PROMARS, it has a VCO 9 Board for its 2nd VCO. This Board is in effect just as the same that the VCO section is only taken out from the Module Board stated herein.

2. VCF and its Peripherals

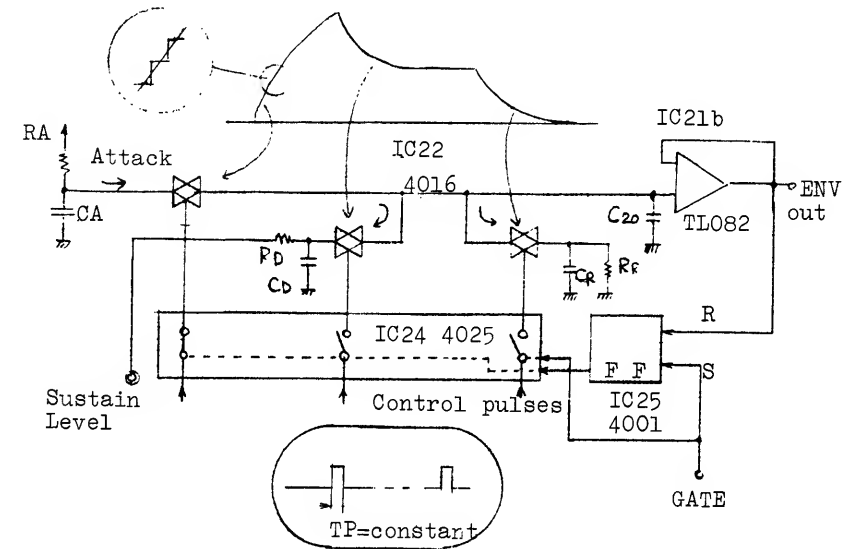

VCF here is not much different from those on the conventional synthesizer. IC11 is the high-pass filter. IC12-IC15 are the low-pass filters. IC17 is the circuit for setting Q for the low-pass filters.

IC18 is the electronic potentiometer to control the depth of the cutoff frequency modulation. IC19 (pins 5,6,7) is the cutoff frequency control mixer. Q8 and Q9 are the antilog current generation circuit.

3. Envelope Generator

There are two Envelope Generators, one each for VCF and VCA. They are basically the circuits to voltage-control the time or the level of A, D, S, R. Since the signals are now in the pulse form, being voltage-pulse converted on the Module Control Board, the A,D and R controls are to be achieved by controlling the number of pulses in a given time. Note that, these pulses here are of so narrow width that it may easily be lost of sight from screen on the oscilloscope if the pulse intervals were extended a little long.

IC25 is the flip-flop which inverts itself on arriving at the attack level. IC24 is the gate selecting the pulse for each of A, D, and R by the timing of the flip flop. IC22 is the analog switch which turns on only when there

is a pulse arrival, thus making C20 to charge-discharge, accordingly. On such charge/discharge, envelopes are developed. The envelopes from C20 are fed through buffer IC21 to obtain low output impedance.

- MODULE CONTROLLER -

Module Controller Board is to control those on Module Board as follows:

- VCO modulation
- VCF modulation
- VCA modulation
- Generation of the clock signals to control ENV GEN.
- Cutoff frequency of HPF
- Pulse width modulation of VCO

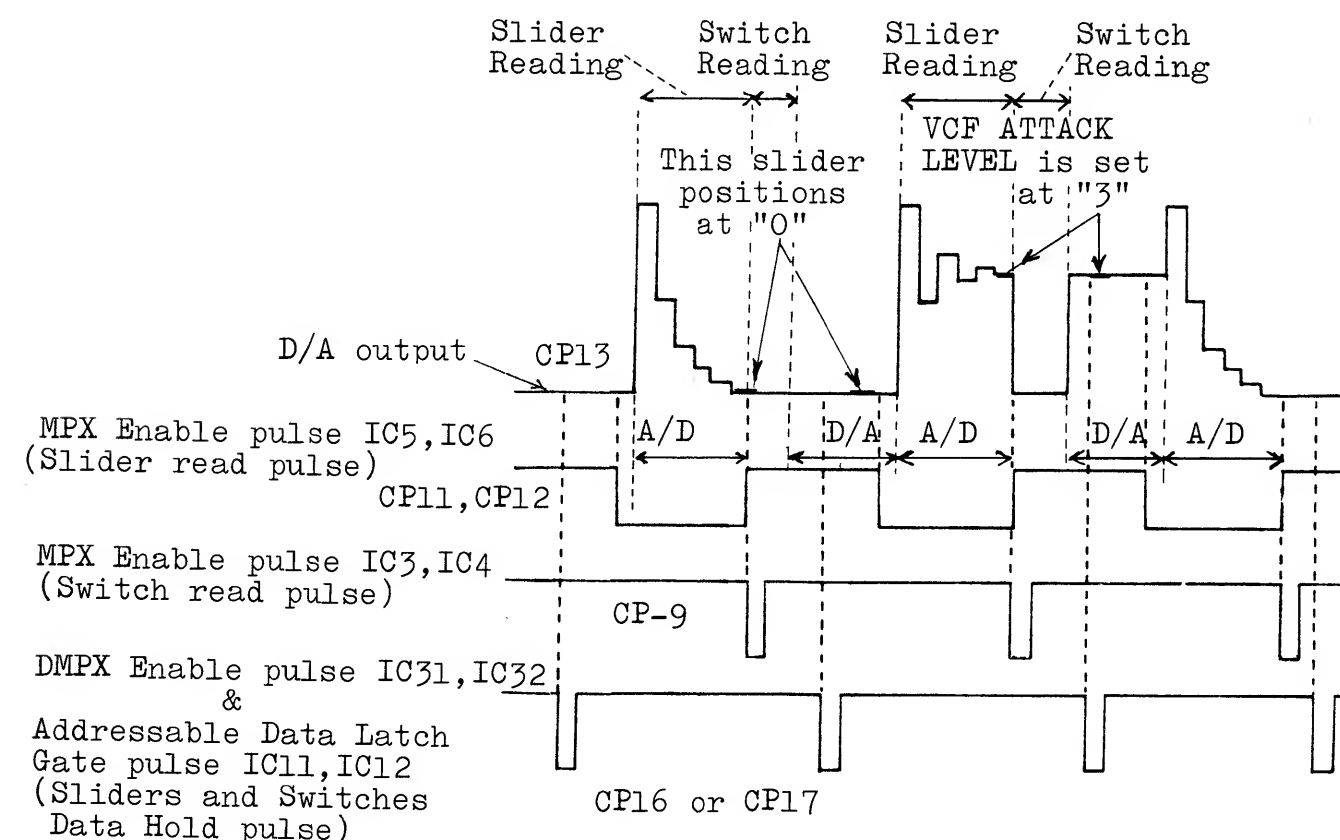

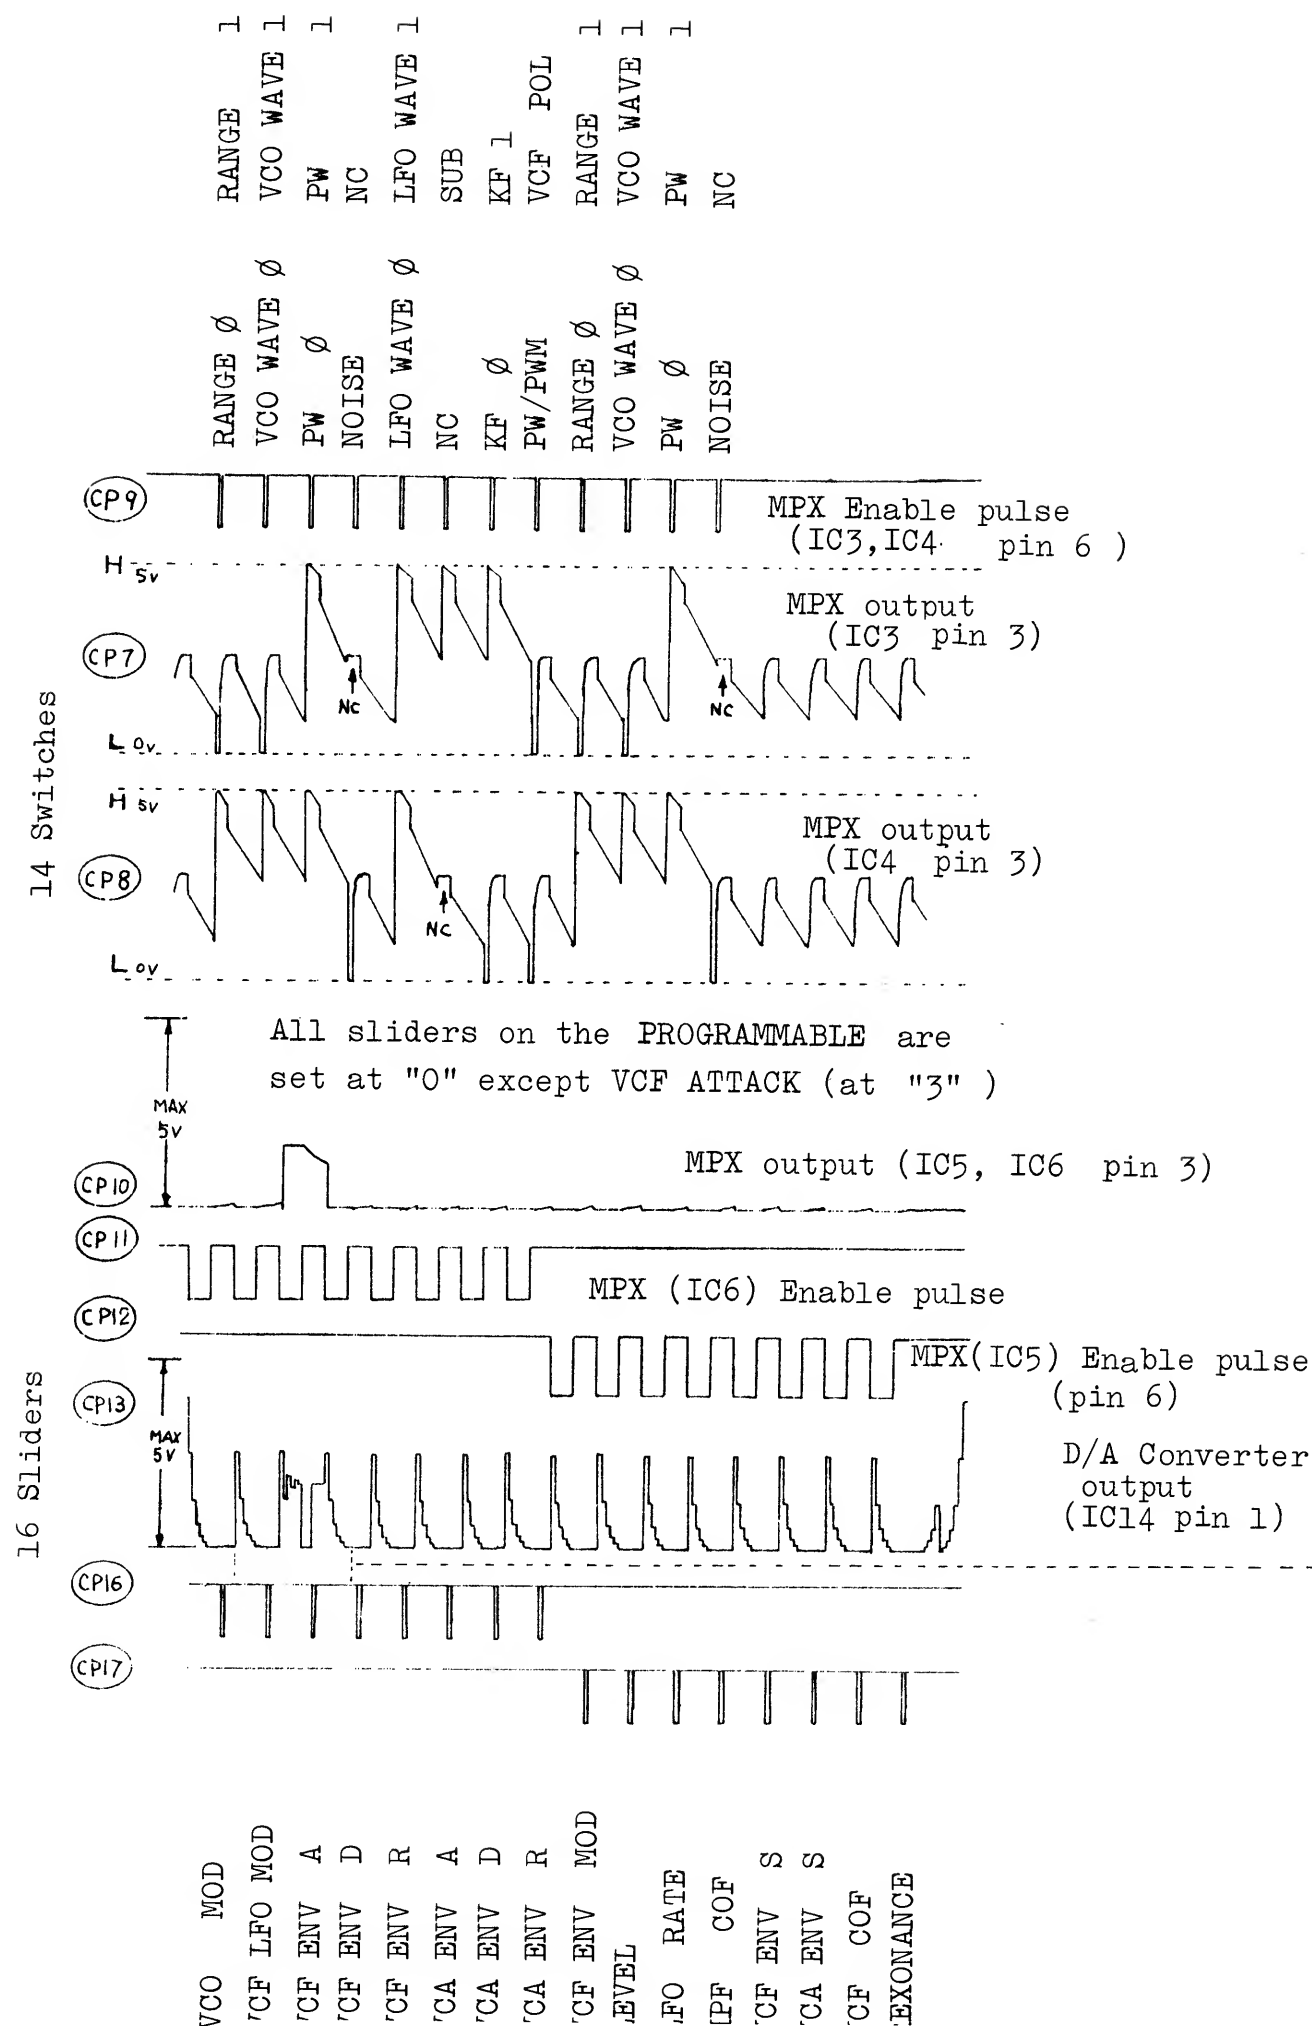

The Module Controller performs these functions by converting the control signals fed from the Mother Board or those fed from the Bender Board into such signals to suit for controlling the modules. Here also included are the Noise Generator and LFO Delay Circuit.

**MOTHER BOARD TIMING DIAGRAM in MANUAL MODE
(SLIDER/SWITCH READ/HOLD, A/D & D/A
CONVERSIONS, MPX and DMPX)**

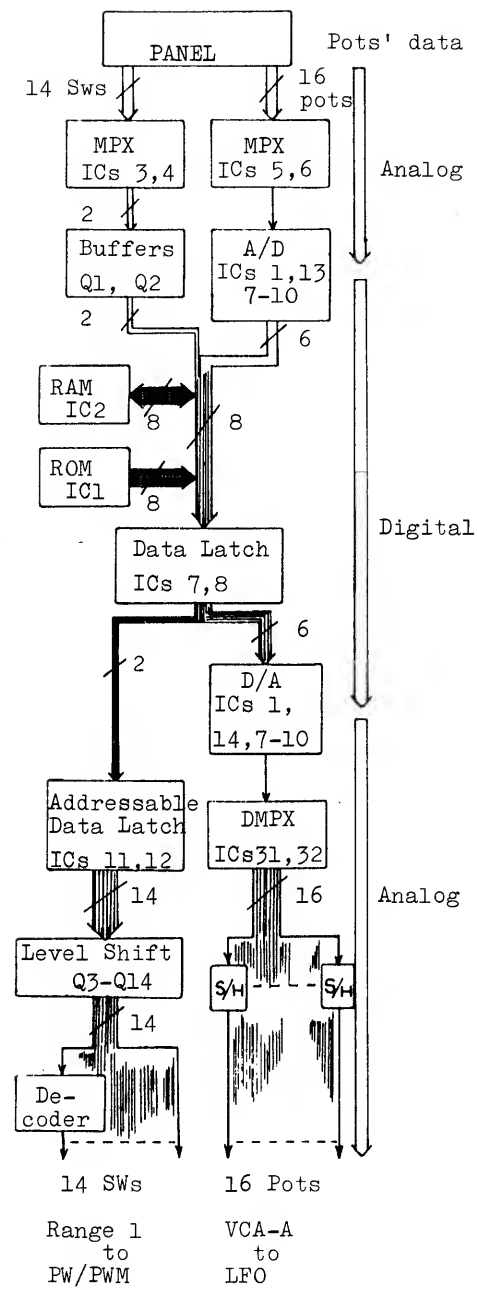

Figure below is part of CP9, 11, 12, 17 and 13 at the left showing functions and timings of A/D, D/A conversions and the Switch reading.

Studying D/A conversion theory on the Mother Board by observing the converter output waveform is very helpful in understanding the operation of microcomputer 8048-012.

1. The computer 8048-012 reads Sliders set positions through A/D conversion.
2. The computer reads, between A/D and D/A conversions, Panel switches status.
3. In Manual Mode, at CP13, final of A/D and D/A outputs are equal in level. This means that Panel Data are fed into Synthesizer Modules as they are. However, in other modes, A/D and D/A show different values because they are out of relation to each other, D/A converter transforms digital data from the memory.
4. During D/A conversion, sliders data being D/A converted from 6-bit format and switch data from 2-bit format are held (latched) and output to the synthesizer modules.

μPD8048

The μPD8048 is an 8-bit parallel computer fabricated on a single silicon chip. The 8048 contains a 1K x 8 ROM program memory, 27 I/O lines, an 8-bit timer/counter and clock circuits. Used in the Compu-Phonic Synthesizers are μPD8048-012 and μPD-8048-011 (JP-4 only) versions in which programs and data dedicated to the Compu-Phonics are stored in the program memories.

VCO-9 BOARD MODULE BOARD

Figures in TP column in the table to immediate right and figures at top of the other tables refer to test points shown in the PCB layout below. The following applies.

1. For sliders; voltage will vary within the range of 0V to +5V as the designated slider is being moved.
2. For switches; the output will be a logical 0 (low) or 1 (high): (0V,+15V), (-15V,+5V), (0V,+5V), depending on the lever position.

MOTHER BOARD OP-104B

(Etch mask 052-364B)

IMPORTANT

In replacing the Mother board, check both the existing board and the new replacement board for existence or absence of Q15 and Q16. If different, see page 19 for modification.

Dotted lines -----
and paranthesisises
with numbers show
original CV-3A
circuit arrange.

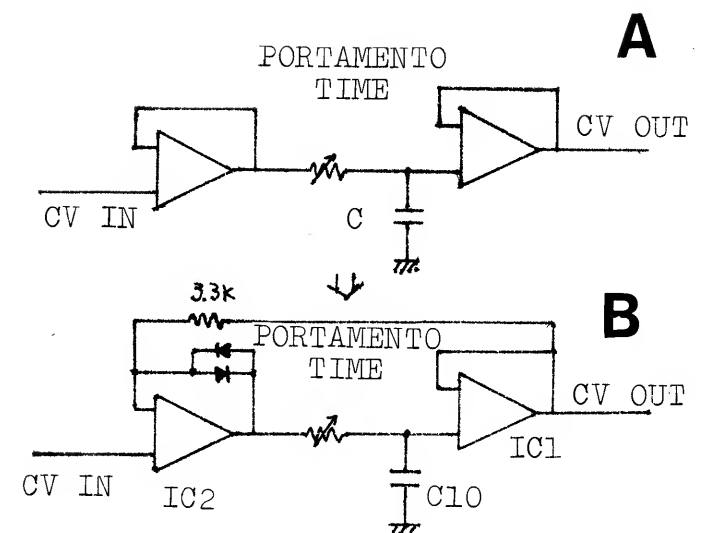

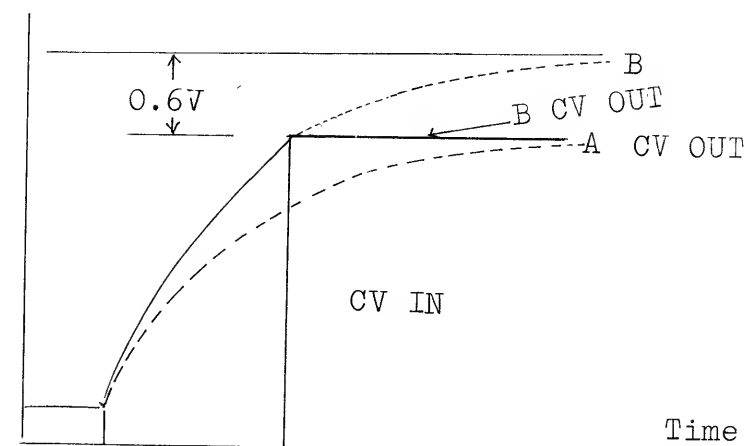

One of the diodes keeps IC2 output 0.6V higher (in the case figure immediately right) or lower than CV IN and C10 charging (discharging) rate is speeded up along curve-B. Once voltage across C10 reaches the CV IN, feedback resistor 3.3K will cause the circuit maintain the CV.

CV-3A (152-003A) (PCB 052-440A)
S/N up to 850729

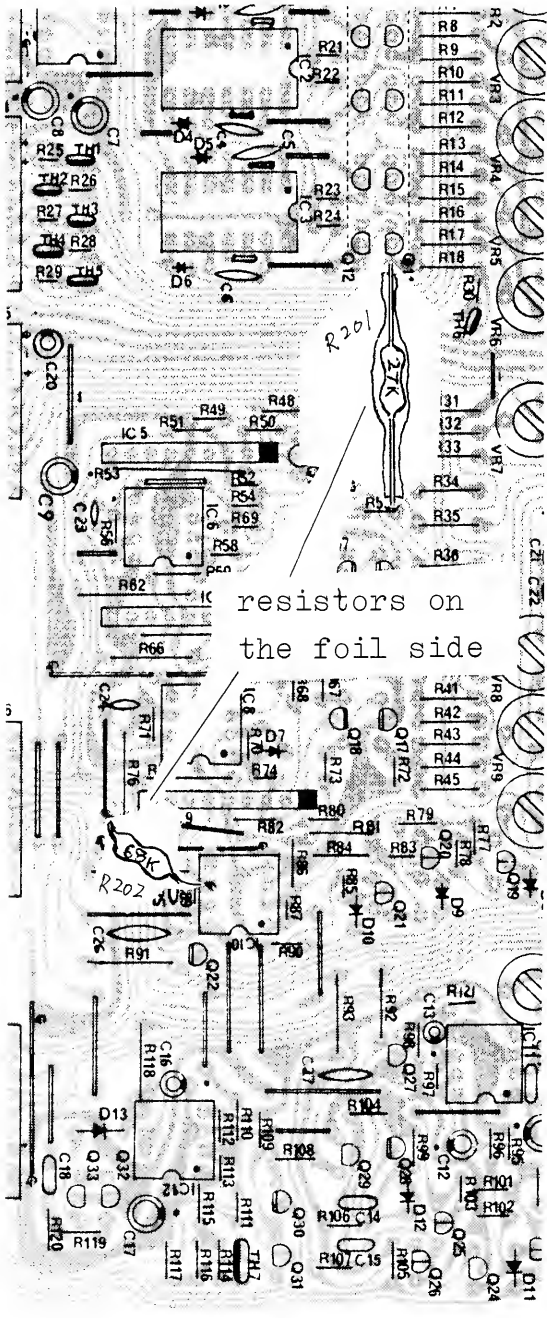

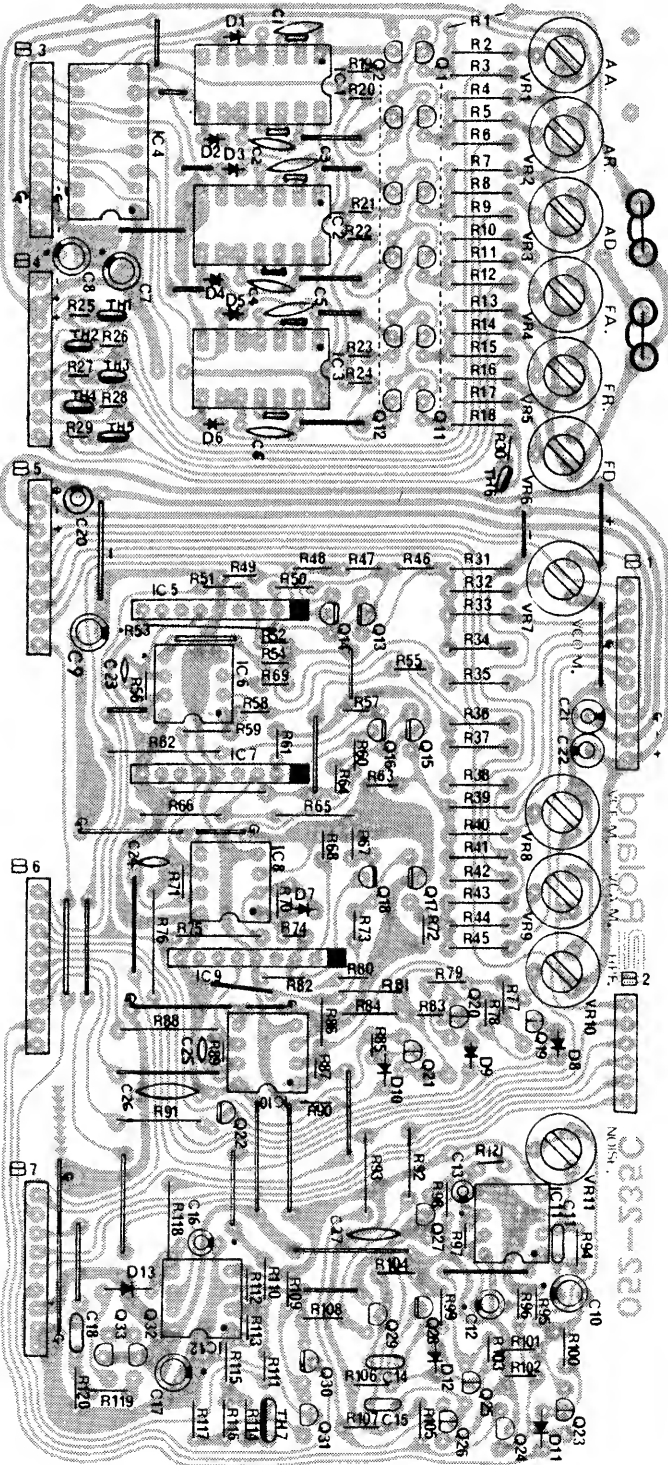

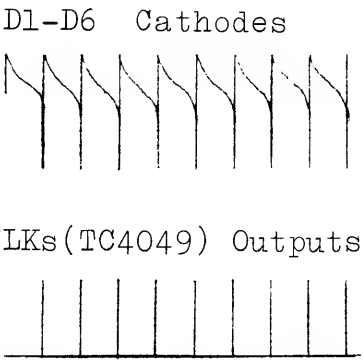

1. PORTAMENTO (with serial number 850370 -- CV-3B)

With Circuit A in the figure right, C charges close to CV IN relatively fast, but will not charge up to the exact CV IN for a while (theoretically, indefinitely).

MODULE CONTROL OP-106C (149-106C)
(PCB 052-235C)

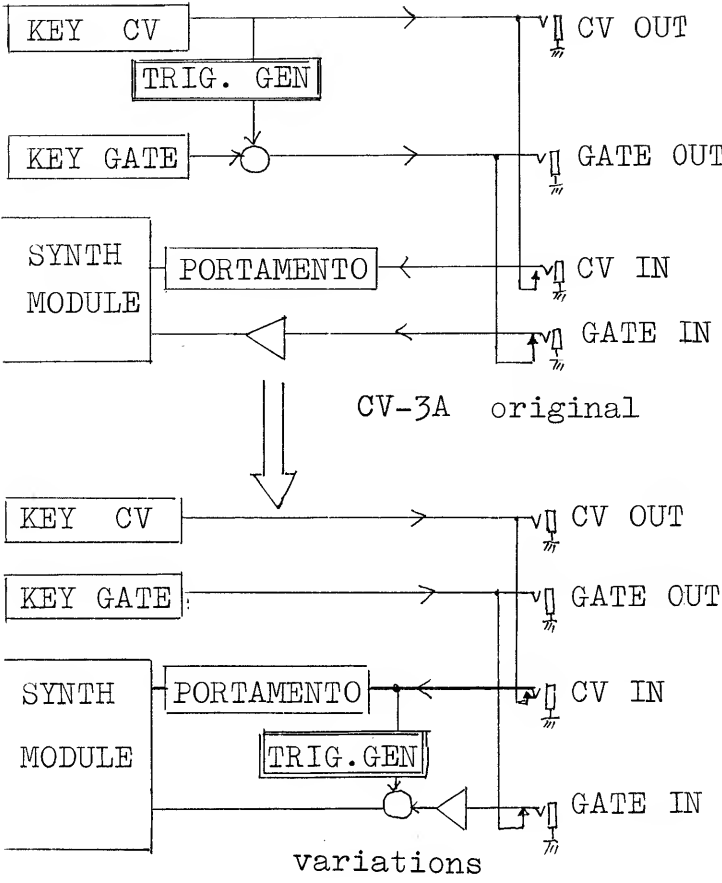

Moving the A, D or R sliders from bottom to top will increase the frequency by approximately 1000.

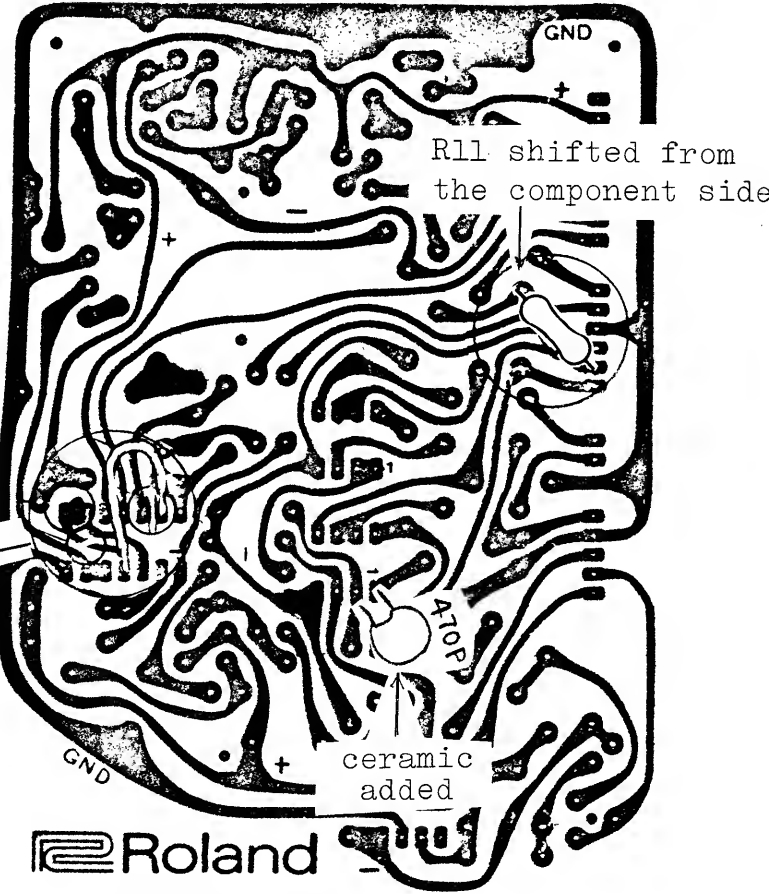

Improvements on CV-3 cont'd
2. Shifting TRIG. GEN. - CV-3A only
This relieves the following:
When keys on MRS-2 are played in legato with the CV and GATE IN/OUT jacks being connected to a CSQ-100, tones corresponding to the subsequent keys can fade away along with the first key's envelope decay(a remarkable example is Preset PIANO).
This is because Gate-retrigger pulse, being blocked with CSQ-100 circuits, does not exist at GATE IN, failing to re-set envelope generator for individual keying that follows to the first keying in sequence.
After modification, MRS-2 has no detrimental effects on sequencers other than CSQ-100.

The modification was conducted on MRS-2 with serial number 840630; besides, products bearing the following numbers have been modified before shipment.

Q4 2SD880-GR or 2SD234-Y

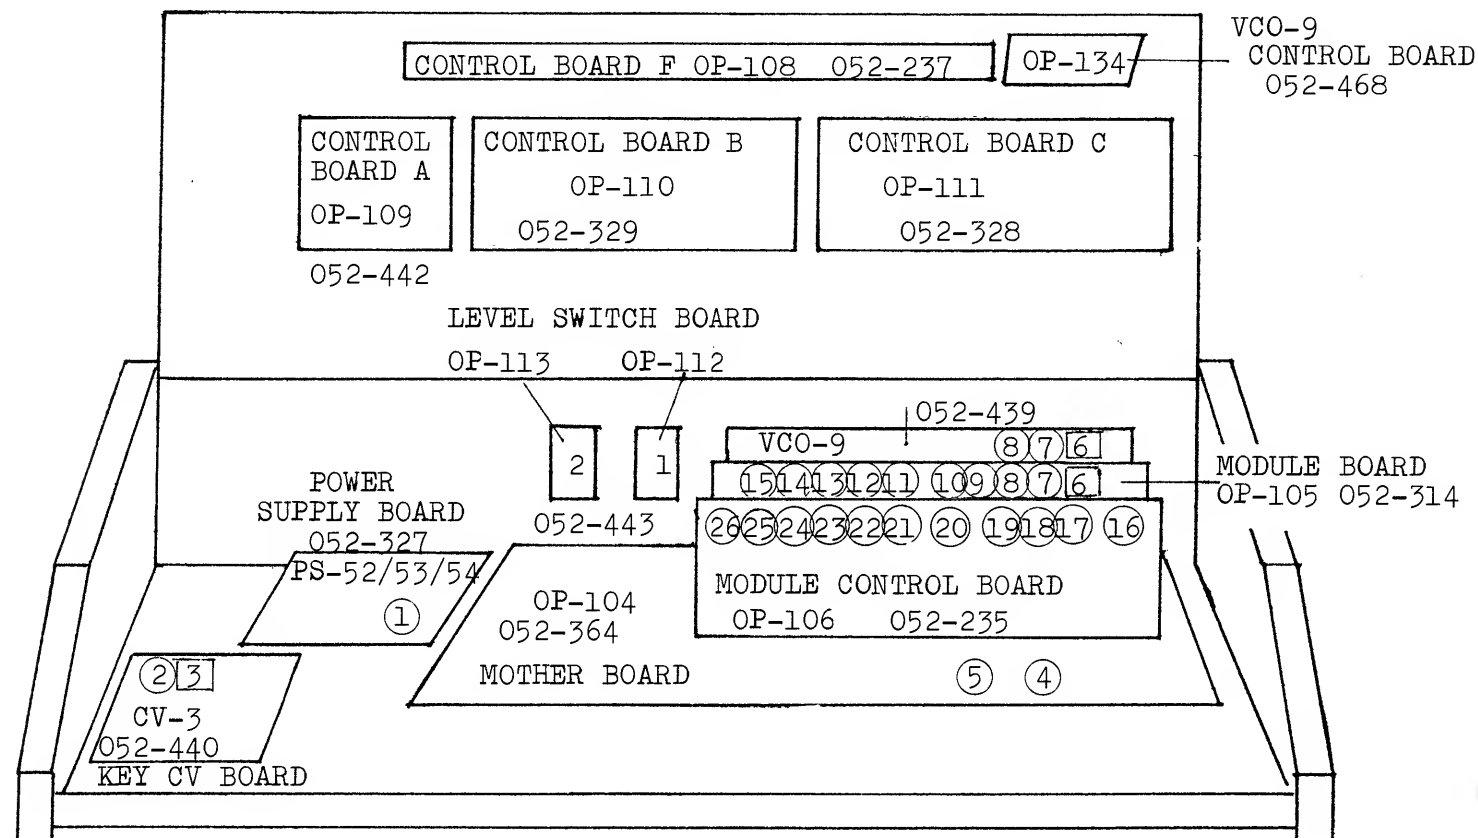

**OP-105E (149-105E)
(PCB 052-314E)**

ADJUSTMENT

Because certain circuits of PROMARS are voltage controlled, Power Supply Board, PS-52/53/54 is the first to be checked and adjusted. Also repairing or replacing PS-** Board forces readjustment of some associated PCBs, CV-3, OP-104, VCO-9 and OP-105.

Replacing a PCB other than Power Supply Board involves readjustment of its own.

Numbers, ①, ②, ③, etc. in above figure show adjusting trimmer potentiometers and are independent of designations in individual circuit diagram.

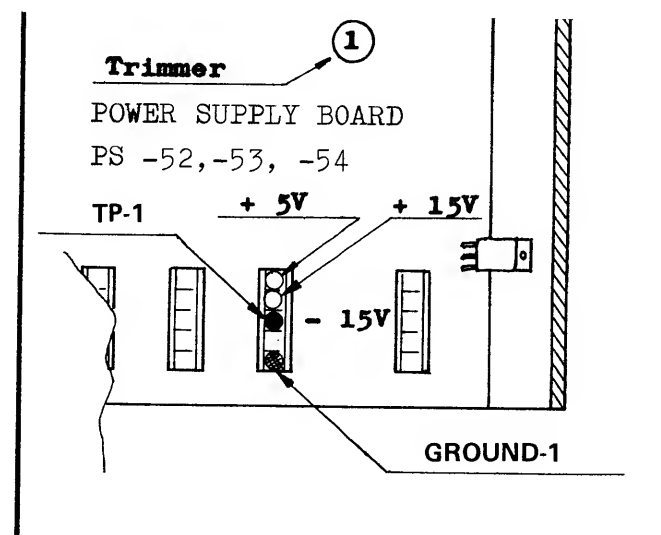

In this adjustment, trimmer pots are abbreviated as "P-xx".

1. DC VOLTAGE (-15 Volt)

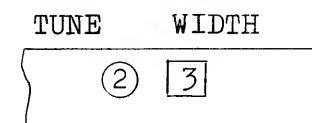

Allow at least five minutes for warmup.

1. Connect a digital voltmeter to TP-1.
2. Adjust P-1 for $-15.0 \pm 10\text{mV}$.
3. Check other voltages, they must be

$+5.0 \pm 250\text{mV}$ and $+15.0 \pm 750\text{mV}$.

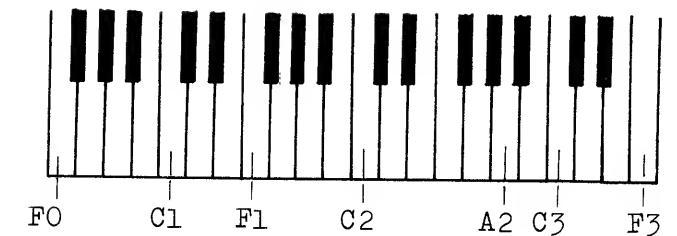

2. KEY CV and WIDTH

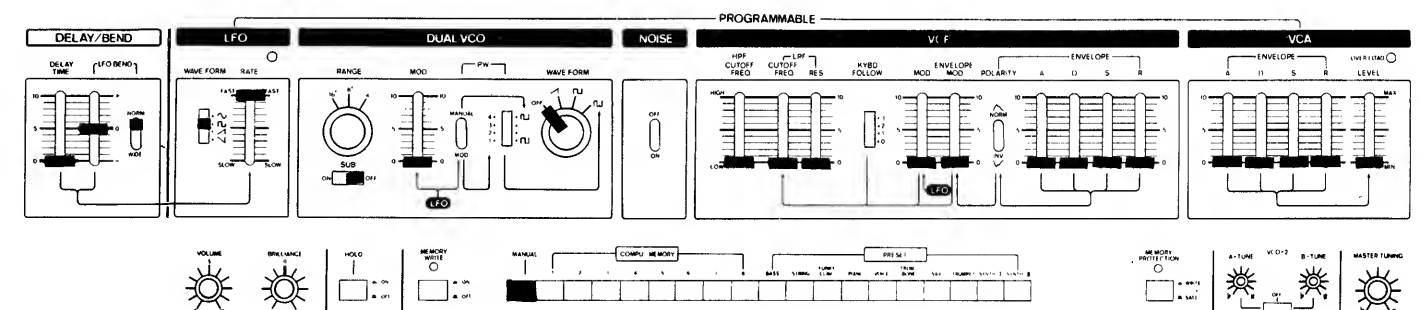

KEY CV BOARD
CV-3

Connect digital voltmeter to the hot terminal on CV OUTPUT jack.

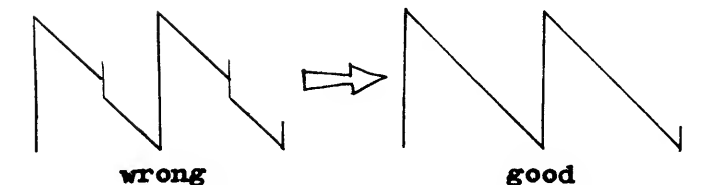

1. While depressing C1 and C2 keys alternately, adjust P-3 so that $C2V = C1V + 1.00V \pm 3\text{mV}$.
2. Hold down C1 key and adjust P-2 to provide $2.00 \pm 2\text{mV}$.
3. Check octave keys for errors:
 $C2 = 3.00 \pm 3\text{mV}$ $C3 = 4.00 \pm 3\text{mV}$

3. LFO WAVEFORM

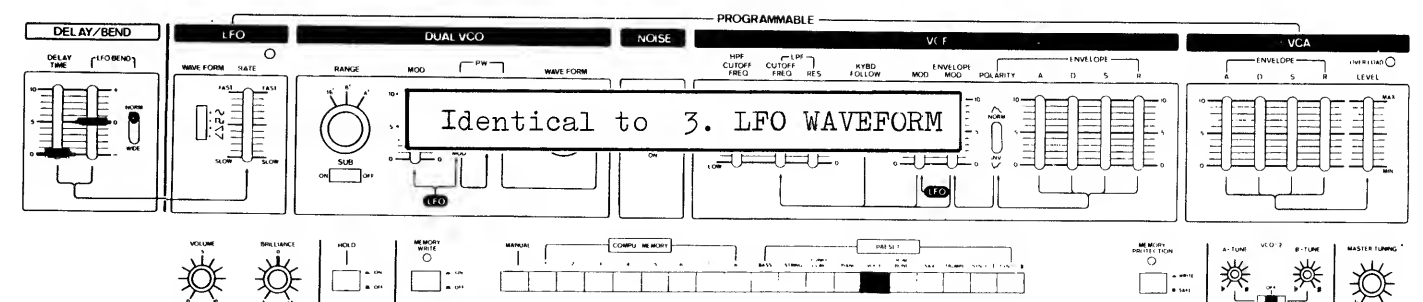

Connect oscilloscope to TP-4 on Mother Board OP-104 (see next page).

1. Adjust P-4 for slope straightness.

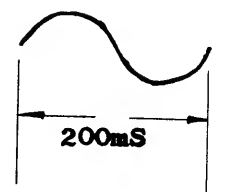

4. LFO RATE

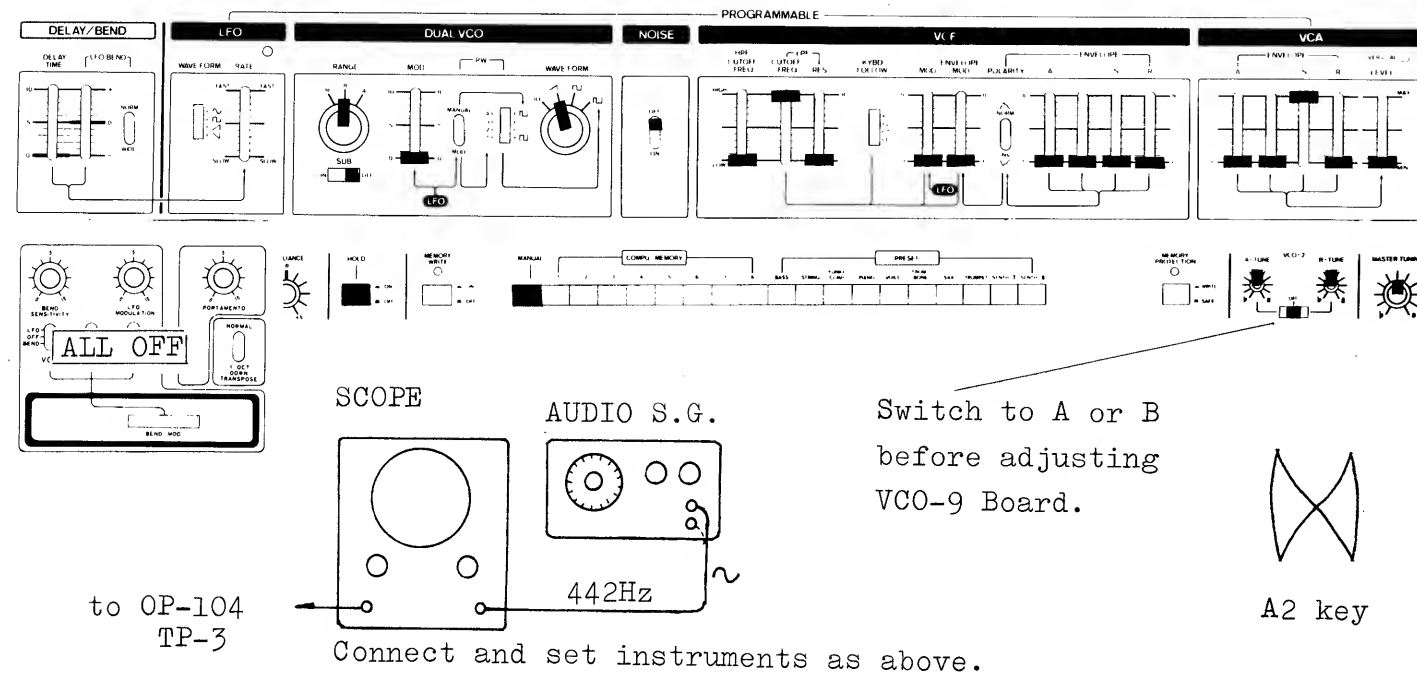

Connect scope to TP-5 on OP-104.

1. Set P-5 for 5Hz.

5. VCO FREQUENCY and WIDTH

MODULE BOARD OP-105

1. While depressing A2 key, Adjust P-7 for 1:2 Lissajous figure.
2. While depressing A0 key, adjust P-6 for 2:1 Lissajous figure.

VCO-9

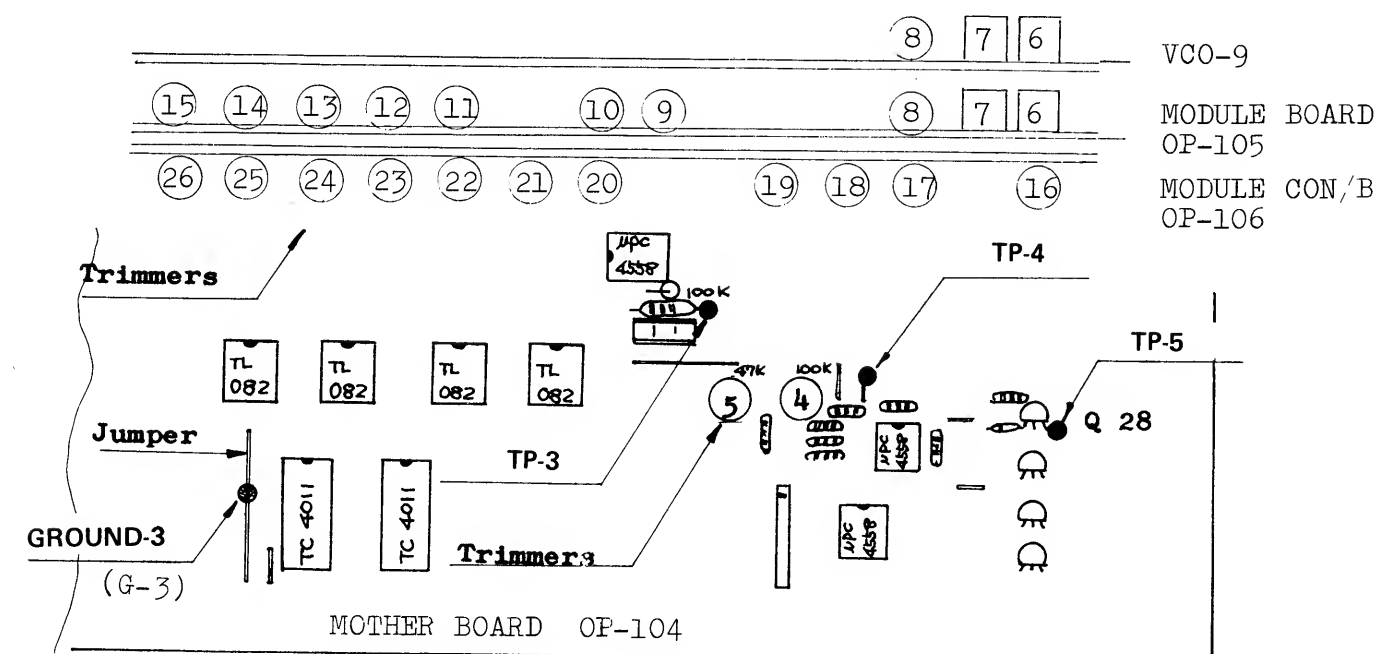

To disconnect VCO-1 signal path:

Pull the housing off the PCB.

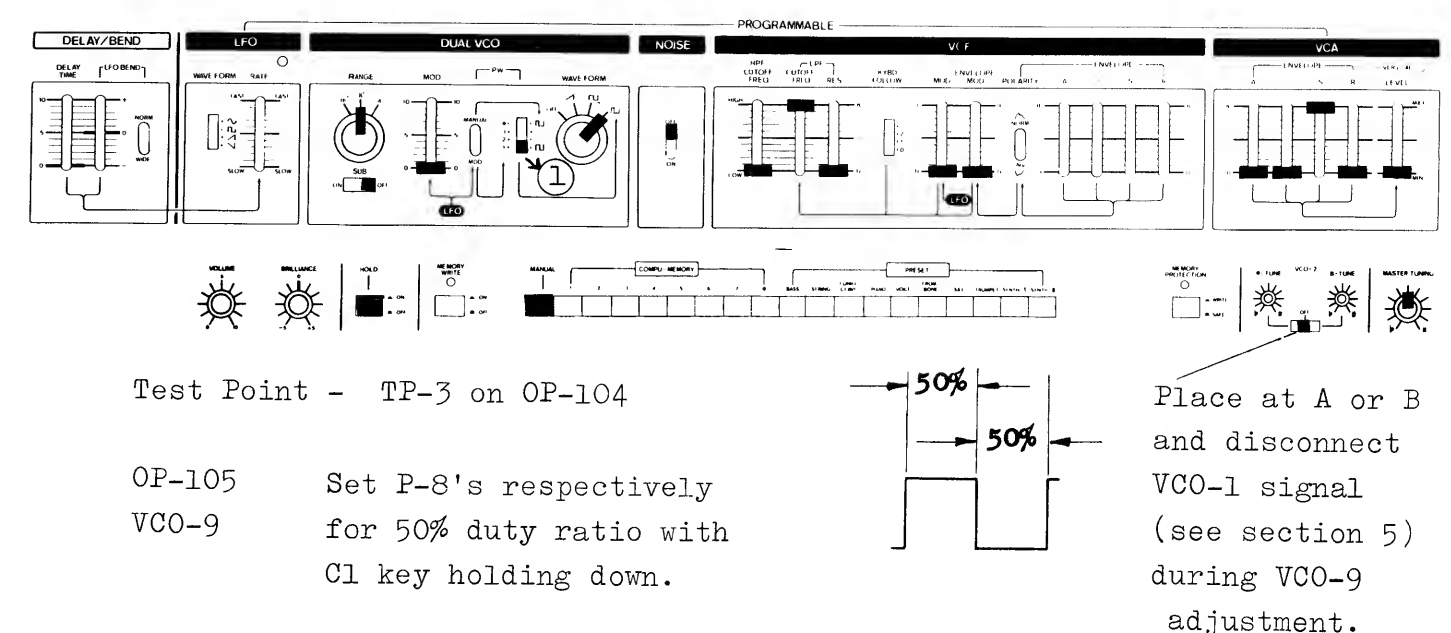

Reverse it and plug in the right pin only.

Set VCO-2 TUNE switch to A-TUNE or B-TUNE.

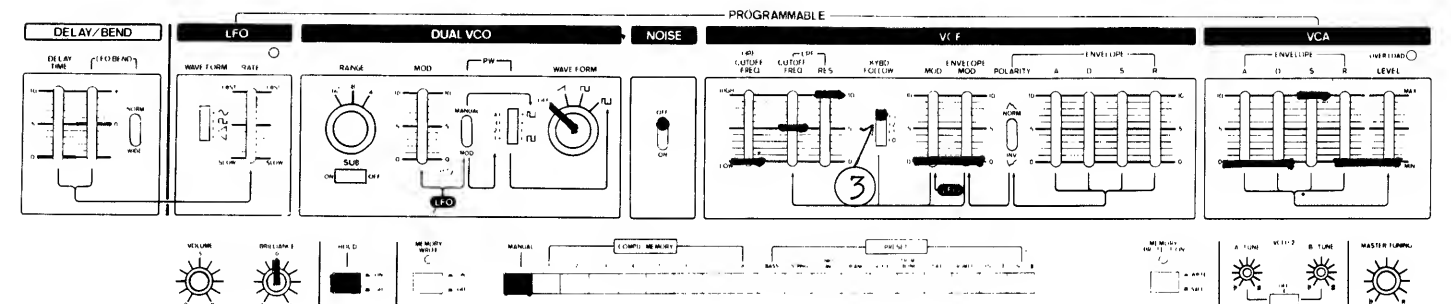

Adjust P-6 and P-7 on VCO-9 Board following the steps in OP-105.

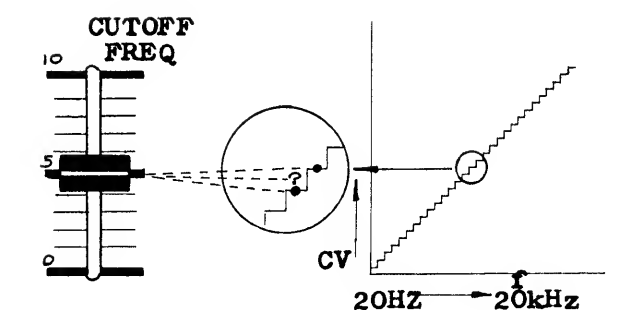

6. VCO WAVEFORM (Pulse width 50%)

7. VCF FREQUENCY and WIDTH

NOTE: Due to the digital control characteristics of this VCF, if CUTOFF FREQ knob is moved steadily and slowly, the resonating VCF will produce frequencies in a series of steps. If CUTOFF FREQ is set at a point exactly between two of these steps, the resulting frequency will be unstable as it jumps up and down between these two steps. The knob must be set at a point near "5" where VCF output frequency locks positively on one frequency or the other.

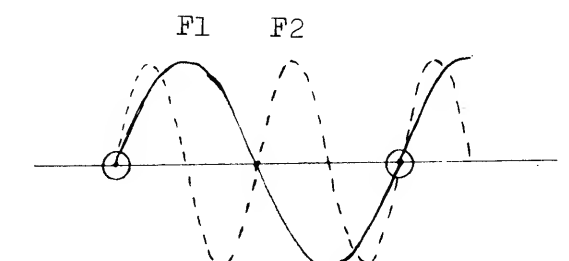

Test Point - TP-3 on OP-104

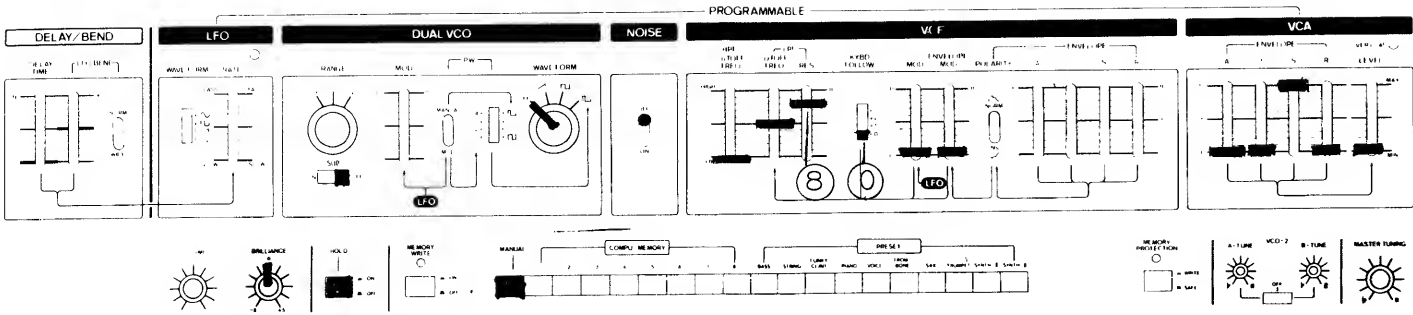

1. While depressing F1 and F2 keys alternately, adjust P-11 on OP-105 to display two figures of 2:1 period.

Reset KEY FOLLOW at "0".

2. Adjust P-12 on OP-15 for 880Hz. (by displaying Lissajous figure, etc.)
3. Check F1, F2 keys for deviations in step 1.

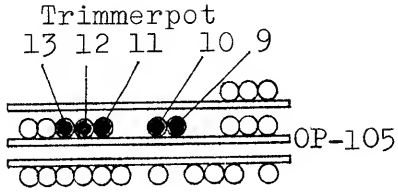

8. VCF RESONANCE

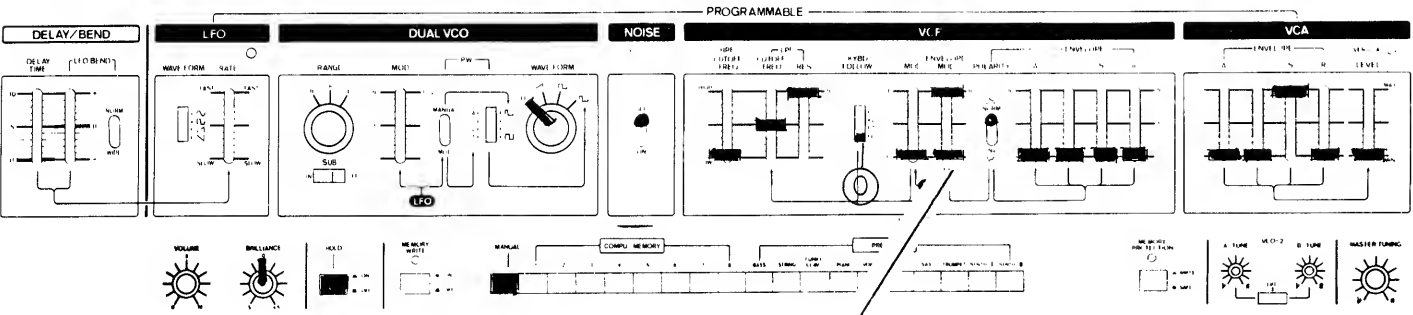

Test Point - TP-3 on OP-104

1. While depressing a key, adjust P-10 on OP-105 so that VCF just begins oscillation.
Approx. 800mVpp sine with RESONANCE set at "8".

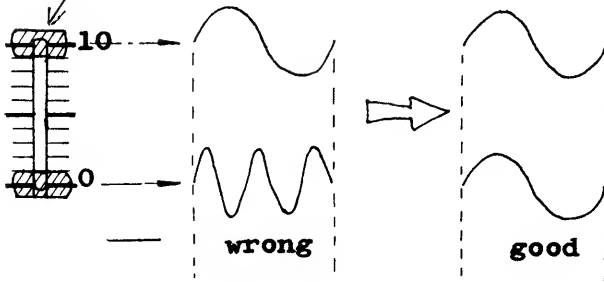

9. VCF ENVELOPE BALANCE

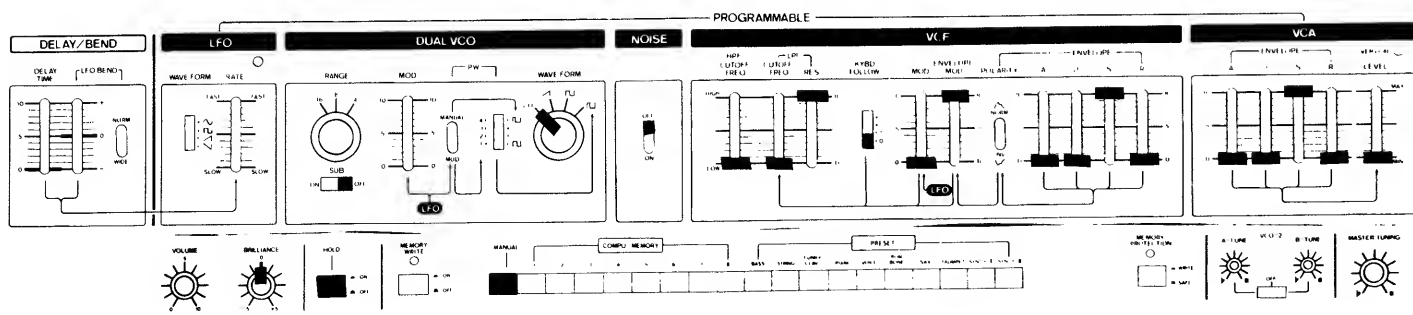

Test Point - TP-3 on OP-104

1. Adjust P-13 on OP-105 so that moving ENVELOPE MOD between "0" and "10" produces no frequency change.

10. VCF ENVELOPE MODULATION DEPTH

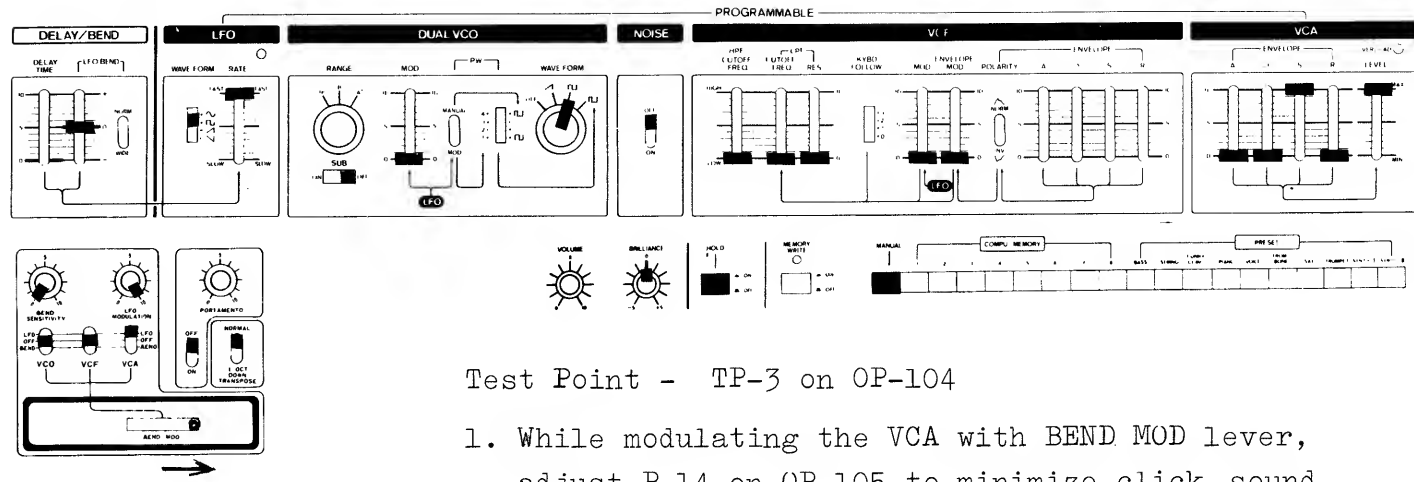

Test Point - TP-3 on OP-104

1. With one key holding down, set P-9 on OP-105 for 12K±1KHz.

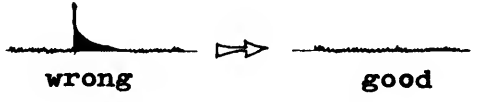

MRS-2

11. VCA BALANCE

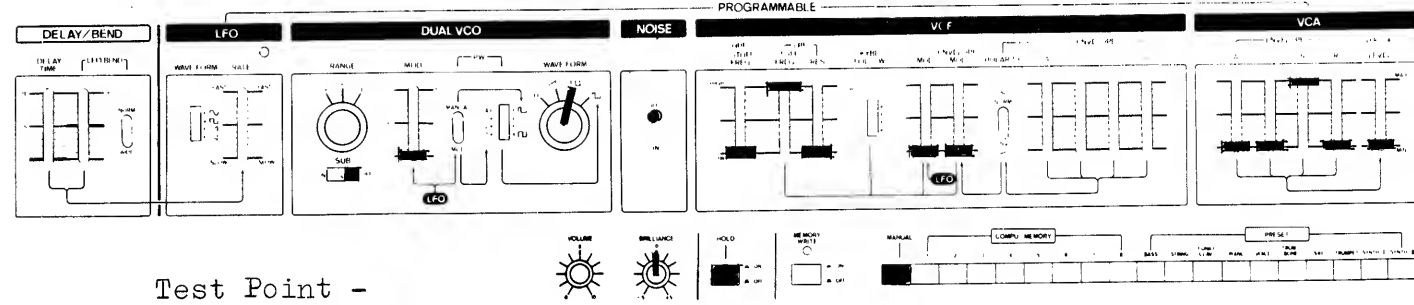

Test Point - TP-3 on OP-104

1. While modulating the VCA with BEND MOD lever, adjust P-14 on OP-105 to minimize click sound.

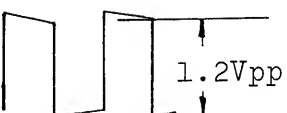

12. VCA LEVEL

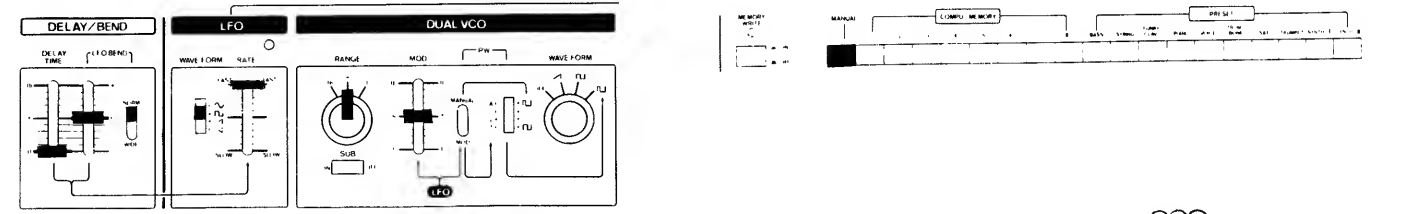

Test Point - TP-3 on OP-104

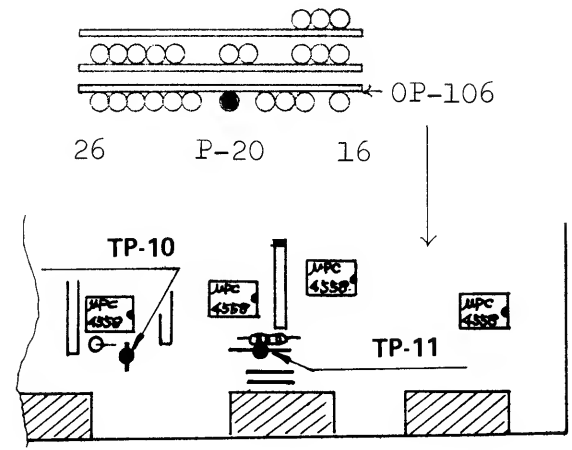

1. While depressing down C2 key adjust P-15 on OP-105 for:

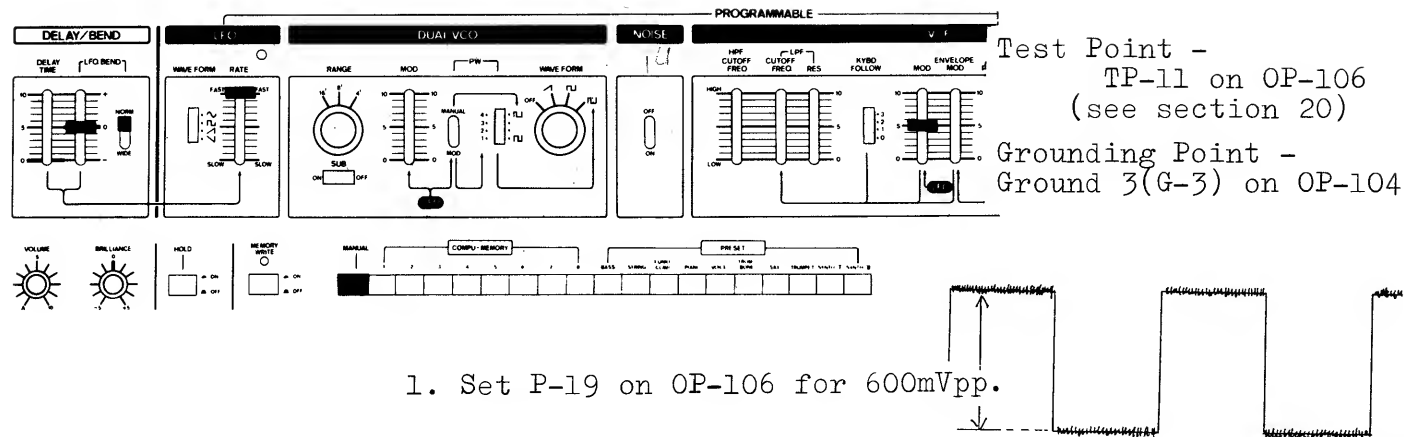

13. LFO VCO MODULATION

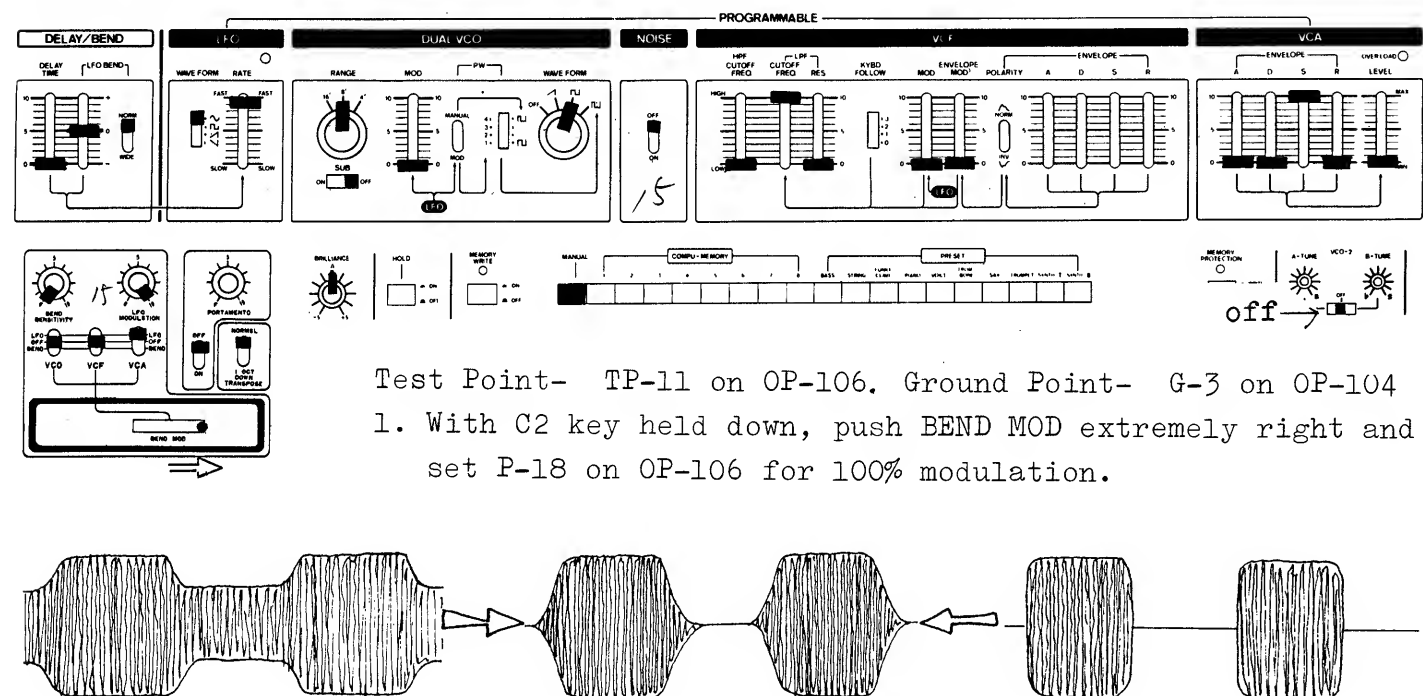

- Test Point - TP-10 on OP-106
Connect scope ground to G-3 on OP-104
1. Set P-20 on OP-106 for 150mVpp ±10%.

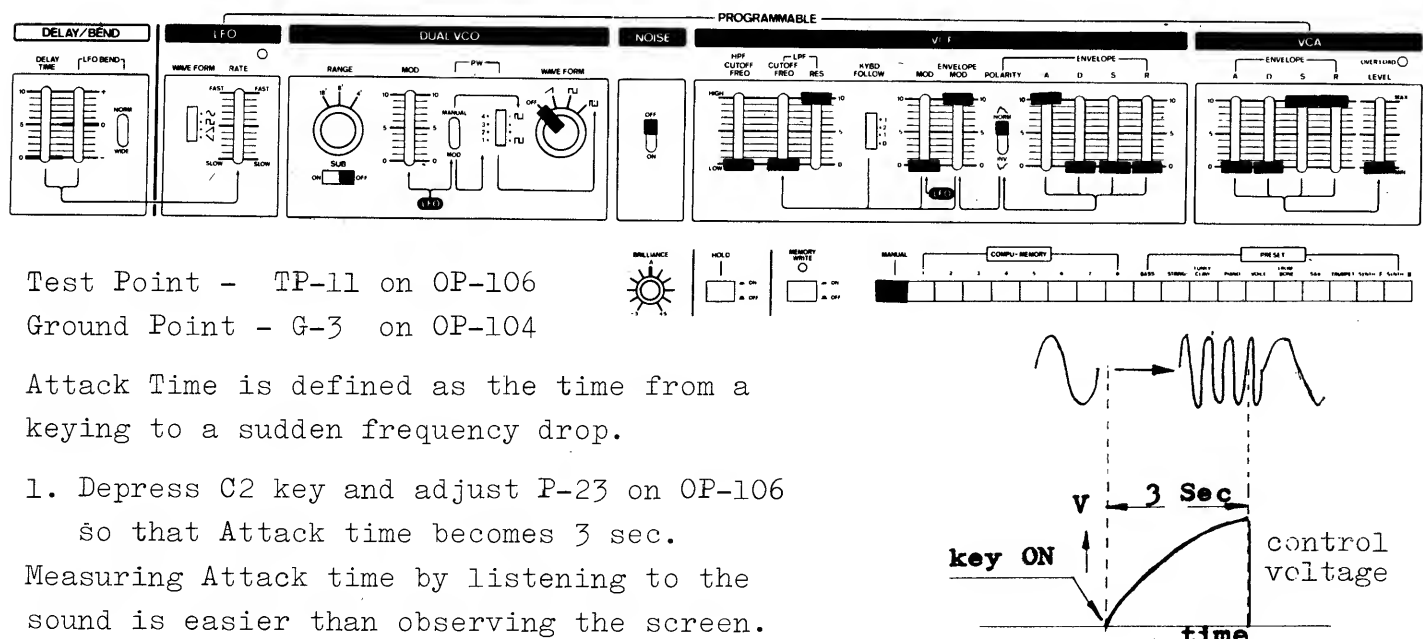

14. LFO VCF MODULATION

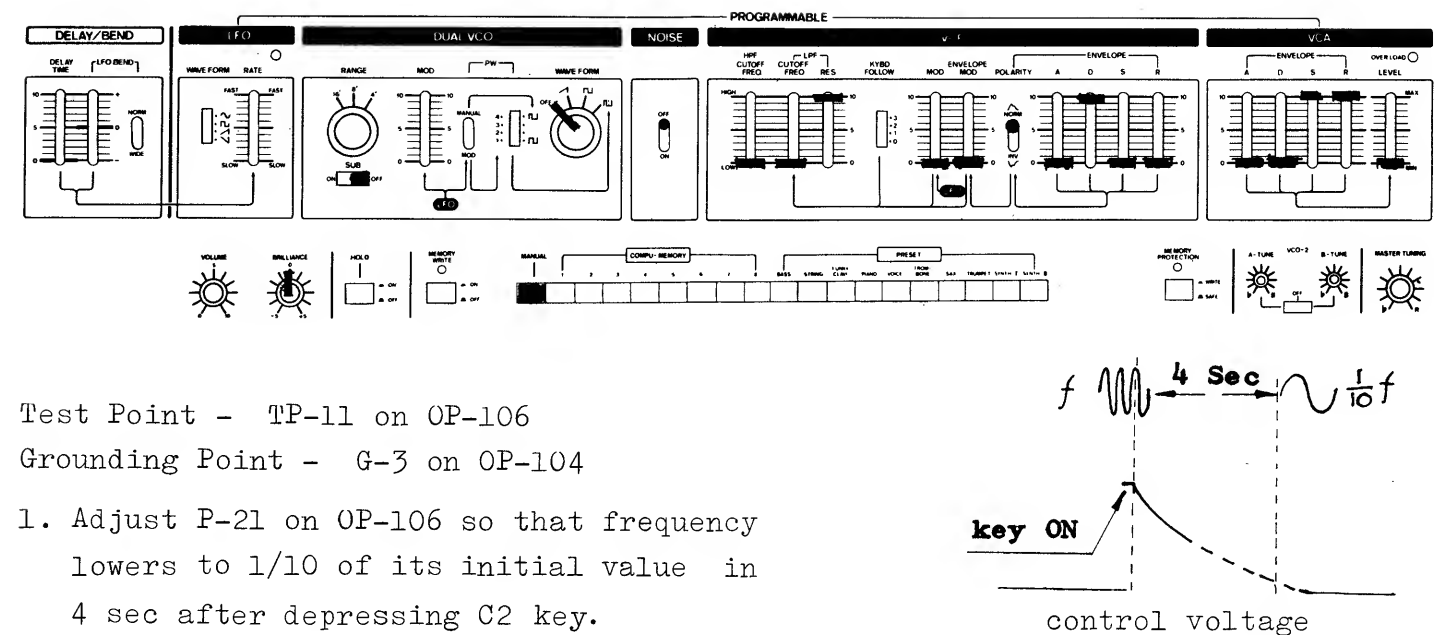

15. LFO VCA MODULATION

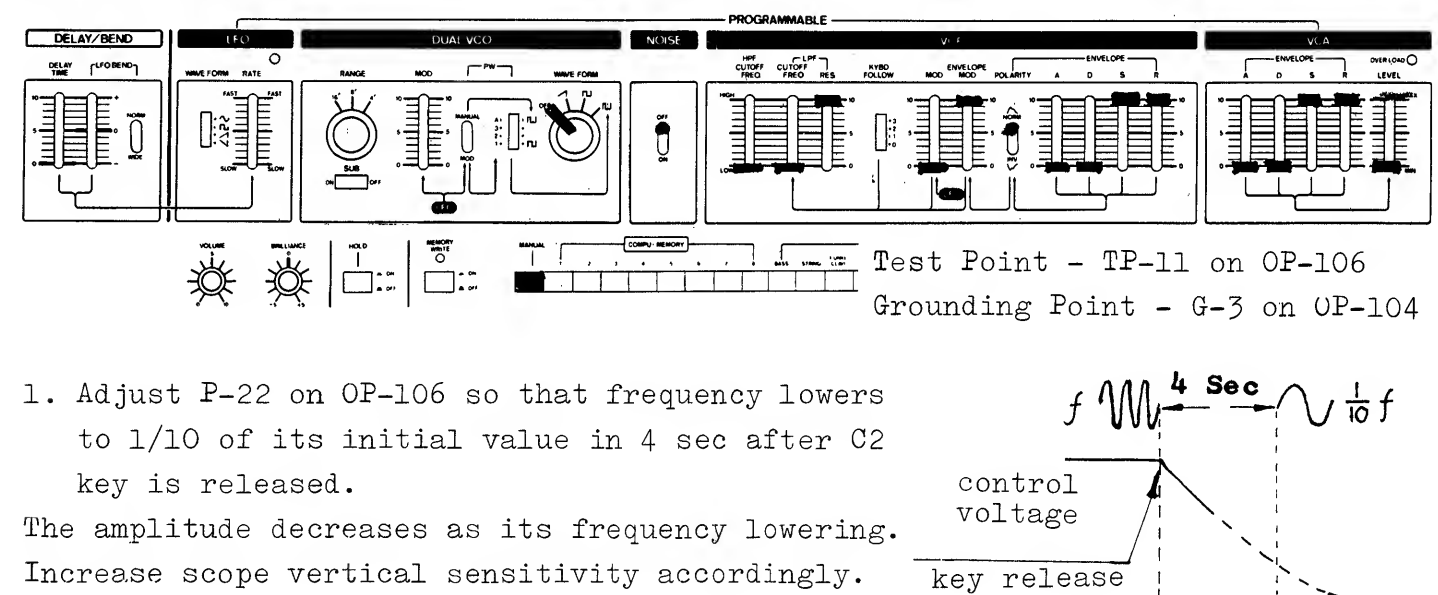

16. VCF ENVELOPE ATTACK

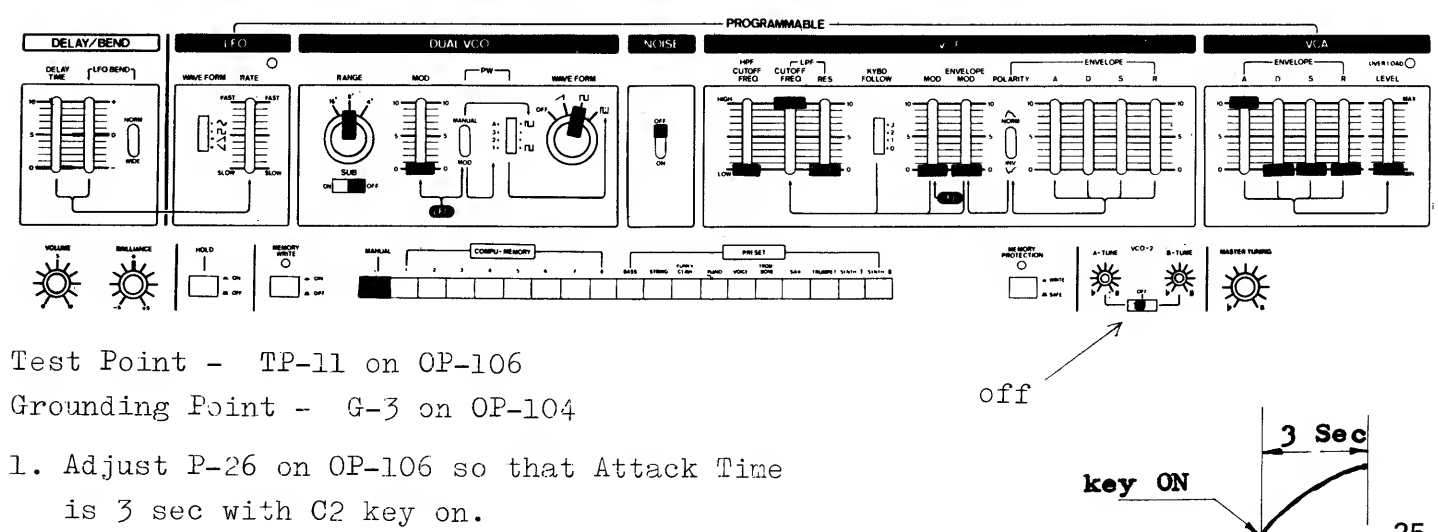

17. VCF ENVELOPE DECAY

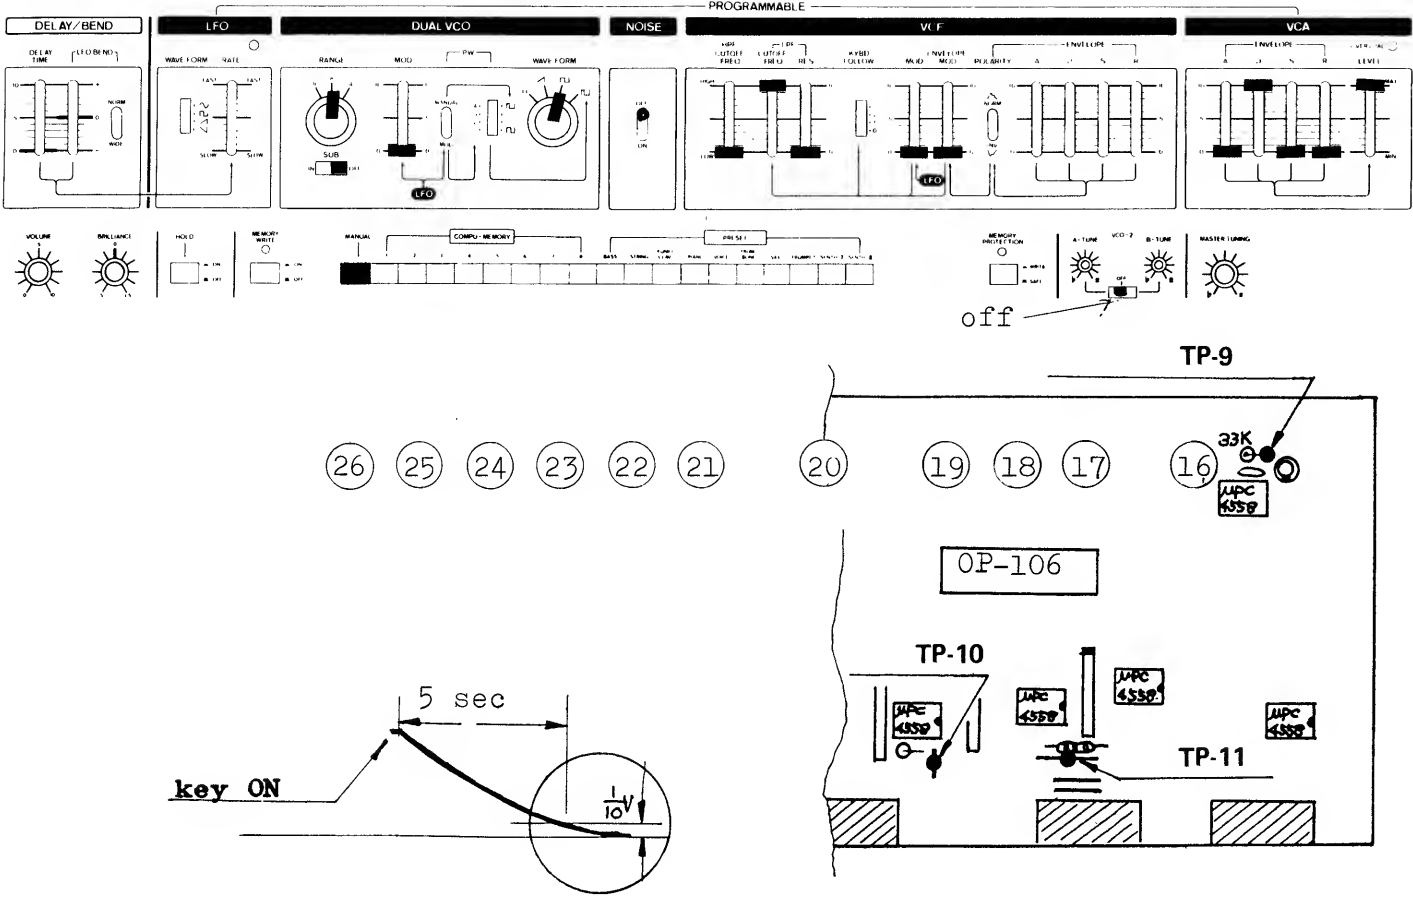

18. VCF ENVELOPE RELEASE

19. VCA ENVELOPE ATTACK

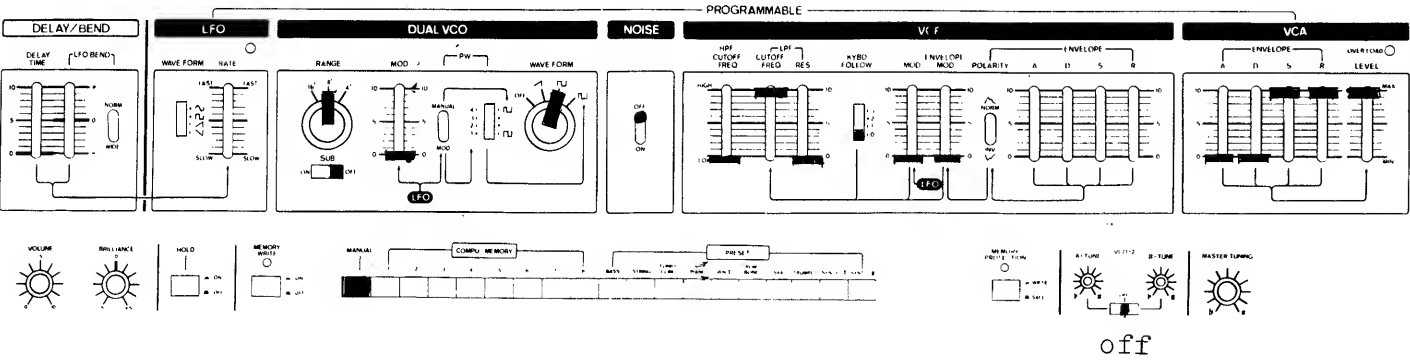

20. VCA ENVELOPE DECAY

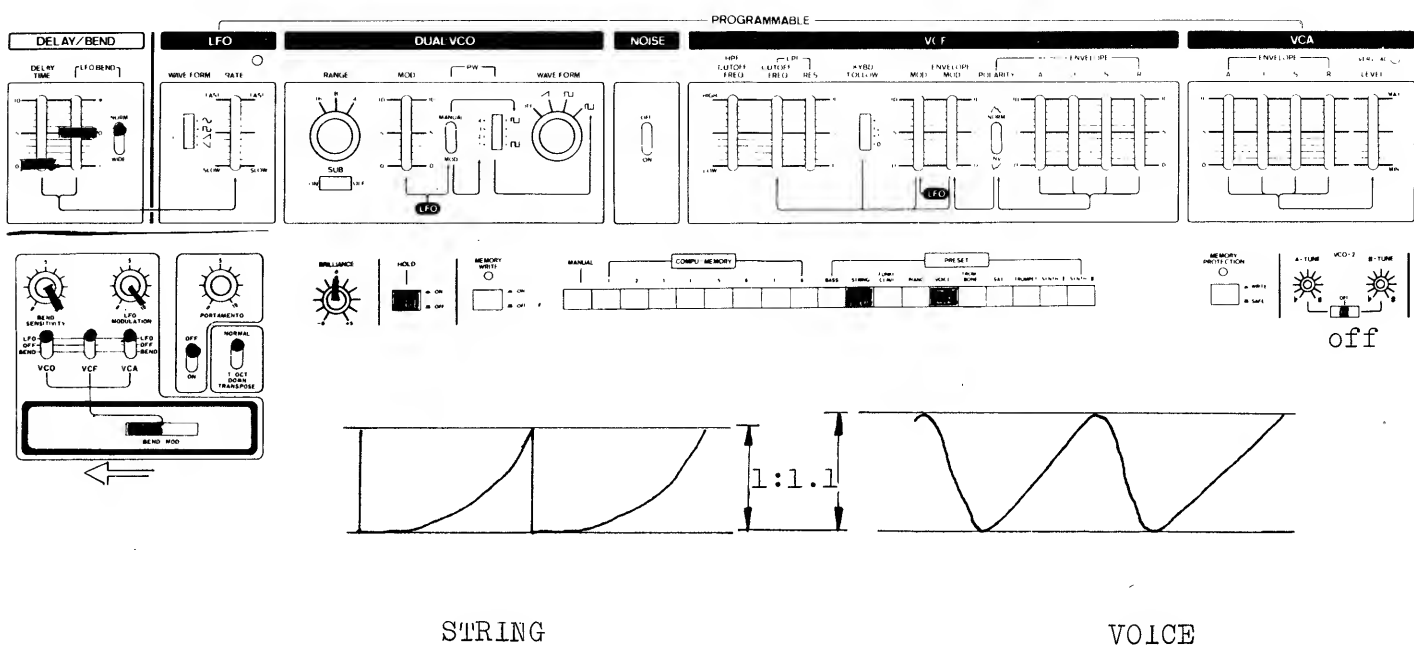

- Test Point - TP-11 on OP-106
Grounding Point - G-3 on OP-104
1. Adjust P-24 on OP-106 so that amplitude decreases to 1/10 in 5 sec after pressing C2 key.

21. VCA ENVELOPE RELEASE

- Test Point - TP-11 on OP-106
Grounding Point - G-3 on OP-104
1. Adjust P-25 on OP-106 so that amplitude decreases to 1/10 in 5 sec after releasing C2 key.

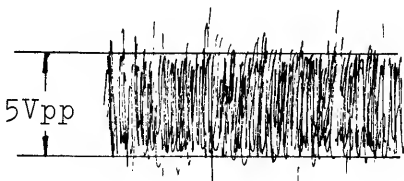

22. HPF CUTOFF FREQUENCY

- Test Point - TP-11 on OP-106
Grounding Point - G-3 on OP-104
1. While pushing BEND MOD lever extremely left, adjust P-17 on OP-106 so that sound ratio of STRING and VOICE becomes 1:1.1 in amplitude.

23. NOISE LEVEL

- Test Point - TP-9 on OP-106
Grounding Point - G-3 on OP-104
1. Adjust P-16 on OP-106 for 5Vpp.
